ENCYCLOPÆDIA BRITANNICA

SEVENTH EDITION.

THE

ENCYCLOPÆDIA BRITANNICA

OR

DICTIONARY

OF

ARTS, SCIENCES, AND GENERAL LITERATURE.

SEVENTH EDITION,

WITH PRELIMINARY DISSERTATIONS ON THE HISTORY OF THE SCIENCES,

AND

OTHER EXTENSIVE IMPROVEMENTS AND ADDITIONS;

INCLUDING THE LATE SUPPLEMENT.

A GENERAL INDEX,

AND NUMEROUS ENGRAVINGS.

VOLUME XVII.

ADAM AND CHARLES BLACK, EDINBURGH;

M.DCCC.XLII.

ENCYCLOPÆDIA BRITANNICA.

Pantograph.

PANTOGRAPH, an instrument contrived for the purpose of copying drawings, so that the copy may either be of the same, of a greater, or of a less size, than the original. It consists of four moveable rulers fixed together by four pivots, and forming a parallelogram. At the extremity of one of these rulers prolonged is a point, which is drawn over the lines of the original drawing, whilst a pencil, fixed at the end of another branch of the instrument, traces on paper the lines of the copy. The pencil is placed in a hollow cylinder, and a weight is added on the top of the pencil; by this means the point of the pencil is made to press on the paper with the force requisite for drawing the lines. The improvements in the construction of different parts of the pantograph described in the *Mémoires de l'Acad. des Sciences*, 1743, have been generally adopted. The pantograph, however, is not found convenient in practice; and, for the purpose of copying maps, plans, and other designs, artists most commonly employ the method of dividing the original design into a number of squares, and the paper on which the copy is to be made into the same number of squares. When this is done, they copy the lines contained within each square of the original, so as to form a similar figure within the corresponding square of the reticula which covers the copy. When the drawing consists of straight lines, a reduced copy is accurately made by means of an isosceles triangle, in which the base is to the side as any line of the copy is to the corresponding line in the original. By setting off with the compasses any line of the original drawing on the sides of the triangle, the base which completes the triangle is the length of the corresponding line to be laid down on the copy. The same operation is performed by the sector.

If a drawing is to be copied, of the same size as the original, without diminution or enlargement, engravers usually trace the copy upon oiled paper laid over the original, or upon the transparent *papier de guimauve* (marsh-mallow paper), made in France.

A pantograph has been made, consisting of a rod, placed vertically, and turning round a fixed point in its length, situated between its upper and lower extremity; the upper end of the rod being a point which is conducted by the hand over the lines of the original drawing, and the lower end being the pencil which traces the copy on paper.

Pantograph.

An instrument upon this principle is sometimes used for drawing the profile of the face, in order to form small portraits or silhouettes.

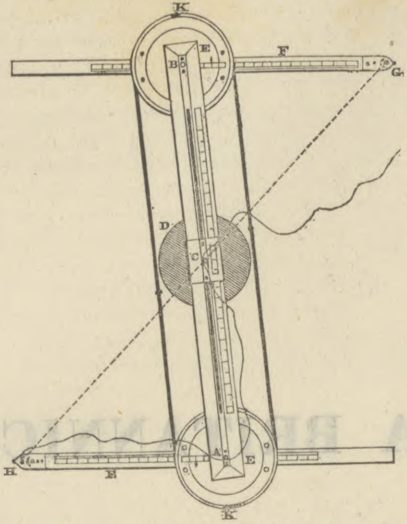
The instrument called micrograph and prosopograph in Puissant's *Géodésie* does not differ in principle from the common pantograph. (B. B.)

A very ingenious instrument for copying drawings, either upon a reduced or an enlarged scale, was invented by Mr Wallace, professor of mathematics in the University of Edinburgh. Of this instrument, which may be fitly introduced under the present head, though differing in *name*, we have been favoured with the following description.

It is a fact well known, that artists of various descriptions, who have frequent occasion to imitate original designs, have long felt the want of a convenient mathematical instrument, by which a copy may be made with neatness and expedition, that shall have any given proportion to the original. The *pantograph* is the only instrument that has hitherto been employed; but although correct and plausible in theory, in practice it is found to be so very imperfect that the artist hardly ever thinks of making use of it.

A consideration of the essential service that would be rendered to the graphic art, by a copying instrument, which should be at once simple in its theory and easy in its application, induced Mr Wallace to turn his attention to the subject; and, in the summer of 1821, he produced the model of a copying instrument, which he has denominated an Eidograph (from *εἶδος* and *γραφω*). The instrument, and its application to the copying of a great variety of subjects, has been shown to engineers, engravers, and other competent judges, in London and in Edinburgh; and their opinion of its utility has been such as to leave no doubt whatever of its completely fulfilling the views of the inventor.

The instrument is represented in the annexed figure.



The *beam*, AB, which is made of mahogany, slides backwards and forwards in a *socket*, C; and the socket turns on a vertical axis, supported by the *fulcrum*, D, which stands on a table. There is a slit in the beam, through which the axis of the socket passes, so that, when the beam slides in the socket, a portion of it passes on each side of the axis. There are two equal wheels, E, E, below the beam, which turn on axes that pass through pipes fixed at A, B, near its extremities; and a steel chain passes over the wheels as a band, by which a motion of rotation may be communicated from the one to the other. There are two *arms*, F, F, which slide in sockets along the lower face of the wheels, just under their centres; at the extremity, G, of one arm, there is a metal *tracer*, with a handle attached to it, by which its point may be carried over the lines in any design; and at H, the extremity of the other arm, there is a black-lead *pencil* fixed in a metal tube, which is ground to fit exactly into a pipe, so as just to slide up or down. In using the instrument, the pencil, in its tube, is raised by a thread which passes over a pulley, and it descends again by a weight with which it is loaded.

From the perfect equality of the wheels, it is easy to see that, if the arms attached to them be placed parallel in any one position, they will retain their parallelism, although one of the wheels, and consequently both, be turned on their centres. Supposing, now, that BC and AC, the parts into which the axis is divided at the centre, have any proportion whatever to each other, if the distances of the tracing point G, and pencil point H, from the centres of their wheels, have the very same proportion, then it follows, from the elements of geometry, that the tracing point G, the centre C, and the pencil point H, will be in a straight line; and further, that CG and CH, the distance of these points from the centre, will have to each other the constant proportion of CB to CA, or of EG to AH. Such being the geometrical property of the *eidograph*, if any subject to be copied be fixed to the table on which the instrument stands, and the tracing point be carried over every line of the design, the pencil point will trace a copy in all respects similar to the original. To facilitate the adjustment of the instrument, so that the copy may have any given ratio to the original, there are scales of equal parts on the beam and the two arms; by these and verniers, both halves of the beam, and equal lengths on the arms, are each divided into 1000 equal parts, and at certain intervals corresponding numbers are marked on them. By means of the scales, when any ratio is assigned, the adjustment is made without the least difficulty. To avoid any derangement by the chain slipping on the wheels, there are *clamps* at K and K, which hold it fast to the wheels at points where it never quits them. They are slackened when the instrument is adjusted.

PANTOMIME, Παντομιμος, amongst the ancients, a person who could imitate all kinds of actions and characters by signs and gestures, without speaking.

The pantomimes formed a part of the theatrical entertainments of the ancients; and their chief employment was to express by gestures and action whatever the chorus sung, changing their countenance and behaviour as the subject of the song varied. They were very ancient in Greece, being, according to some, derived from the heroic ages; but however this may be, they were certainly known in Plato's time. In Rome, it was as late as the reign of Augustus before they made their appearance. With respect to their dress, it was various, being always suited as near as possible to that of the person they were to imitate. The *crocota* was much used amongst the Roman pantomimes, in which, as well as in other female dresses, they personated women.

"The pantomimes," says Gibbon, "who maintained their reputation from the age of Augustus to the sixth century, expressed, without the use of words, the various fables of the gods and heroes of antiquity; and the perfection of their art, which sometimes disarmed the gravity of the philosopher, always excited the applause and wonder of the people. The vast and magnificent theatres of Rome were filled by 3000 female dancers, and by 3000 singers, with the masters of the respective chorusses. Such was the popular favour which they enjoyed, that in a time of scarcity, when all strangers were banished from the city, the merit of contributing to the public pleasures exempted them from a law which was strictly enforced against the professors of the liberal arts."

Pantomimes are still very common. In some respects indeed they differ from those of antiquity; but they retain the name, and, like these, they consist in the representation of things merely by gestures.

PANWELL, a town of Hindustan, in the province of Aurungabad, situated on the banks of the Pan, about seven miles from its mouth. It is an extensive place, and carries on a considerable trade. There are still here the remains of a brick fort built by the Mahratta chief Sevajee about the year 1680, to protect the inhabitants against the incursions of the Siddees. Panwell now belongs to the British. It is twenty-seven miles east of Bombay. Long. 73. 13. E. Lat. 19. N.

PANY ISLE, one of the Philippines, 110 miles in length by thirty-eight in average breadth. It is situated due south of Luzon, between the 122d and 123d degrees of east longitude. The island is marshy, and consequently unhealthy. When viewed from the sea, it exhibits numerous villages on the declivity of the hills, the houses of which are generally well built, and arranged with great regularity. In the interior are found deer, hogs, buffaloes, and wild animals; and cattle and horses range at pleasure through the uncultivated parts. The inhabitants manufacture handkerchiefs and cloths from cotton, and from the fibres of another plant, with which they supply the neighbouring islands. It has the reputation of containing gold and silver mines. The principal establishments of the Spaniards on this island are at Ilo-ilo and Antigua, on which coast there is good anchorage in ten fathoms, at a considerable distance from the shore. There is no security here either for life or property. The principal settlement, Antigua, is extremely ill governed and defended, vessels being plundered in the harbour by the pirates, who carry their crews into slavery. Long. 122. 33. E. Lat. 11. 15. N.

PAO, SAN JUAN DEL, a town of Columbia, in South America, about fifty leagues south-west from Caraccas. It is situated on the river Pao, the course of which was turned about the end of the seventeenth century, and, instead of flowing into Lake Valencia, directed into the Portugueza, a branch of the Apure, which itself is an affluent of the Orinoco. The town consists of several handsome streets, has a neat parish church, and is inhabited chiefly by the proprietors of the cattle reared on the fertile plains which surround the town. It contains a population of between 5000 and 6000. Lat. 9. 20. N.

PAO-KING, a city of China, of the first rank, in Houquang, situated on the river Lokyang, by which it communicates with the great lake Tongting.

PAOLA, a city of Italy, in the province of Calabria Citeriore, of the kingdom of Naples. It stands on the side of a hill, about one mile from the sea, and contains several churches and monasteries, 650 houses, and 4500 inhabitants, who are chiefly employed in making wine and oil, and in the manufacture of earthenware.

PAOOM, one of the smaller of the New Hebrides, in the South Pacific Ocean, and which appeared to Captain Cook to be two islands. Long. 168. 20. W. Lat. 16. 30. S.

PAOTING, a city of China, of the first rank, in the province of Pe-che-lee. It is the residence of the viceroy, and ranks next to Pekin amongst the cities of the province. It is seventy-seven miles south-south-west of Pekin. Long. 115. 14. E. Lat. 38. 54. N.

PAPA, a town of the Austrian kingdom of Hungary, in the province of the Hither Danube, and the circle of Weszprimer. It contains a palace of Esterhazy, a Catholic, a Lutheran and a Reformed church, with a seminary belonging to the last of these religious sects. There are 780 houses, with 5150 inhabitants, who grow some excellent wine. Long. 17. 20. 55. E. Lat. 47. 19. 32. N.

PAPAL STATES. Under the article ITALY we have traced the origin and growth of the temporal power of the Roman pontiffs. In the article ROME we shall exhibit a view of the rise and progress of that great state which, first as a republic, and subsequently as an empire, obtained the command of the western world The present article will be limited to a view of the temporal dominions of the sovereign pontiff, in the state in which they actually exist.

This territory is situated in the centre of Italy, being bounded by the Adriatic Sea on the eastern, and the Mediterranean on the western side. It extends in north latitude from 41. 9. 8. to 44. 49. 54., and in east longitude from 10. 26. 2. to 12. 49. 30. The whole is connected together, with the exception only of two small portions. One of these is the dukedom of Benevento, which is surrounded by the Neapolitan province of Principato Ulteriore; and the other the principality of Pontecorvo, enclosed within the province of Terra di Lavoro, belonging to the same state. The papal dominions are bounded on the north-western side by the Austrian kingdom of Venetian Lombardy, on the north-eastern by the Adriatic Sea, on the south-eastern by the kingdom of Naples, on the south-western by the Mediterranean Sea, and on the west by part of the grand duchy of Tuscany and a portion of the duchy of Modena. As the two seas, which form partly the eastern and western boundaries of the papal dominions, afford supplies of food, and might be made the means of considerable foreign trade to a more active and enterprising people, they deserve to be noticed. A short description of the shores, the harbours, and the bays, may also be of interest.

The western coast of the pope's dominions is by far the shortest. It commences a little to the south-east of Orbitello, in the Tuscan territory, and proceeds by a bay, not deep, to Civita Vecchia. It has no towns on the shore; but about three miles inland, and visible from the sea, are the cities of Montalto and Corneto, neither of which has any foreign trade. Civita Vecchia is the principal seaport on this side. It is well fortified with good walls and ditches, several half-moon batteries, and various other works; and upon a peninsula is a fine castle, from which a mole is projected, whilst another mole about 180 fathoms in length is carried into the sea. Between these two is the harbour, having seventeen feet of water at one of the entrances, and twelve feet at the other. Ships are safe everywhere within the harbour, and have twenty feet of water. Proceeding to the south-east of this port, the church of St Peter's at Rome is visible nearly the whole of the course, but more distinctly after passing the Cape Linaro. There are only a few miserable villages upon the shore; but the small towns of Marinella, Palo, and Montcrone, about two miles from the sea, are visible. The river Tiber has two outlets to the sea, which are divided by the Isola Sacra, a tract of land about half a league in breadth. Of these, the first or northernmost is called the Bocca del Fiumecino, and the second Bocca de Fiumara. All the land near and about the mouths of the Tiber is low and marshy, and not easily distinguishable from the water; which renders the approach dangerous, especially when, as is often the case, it is covered with dense fogs. The only mouth of the Tiber for vessels is the Bocca del Fiumecino. It has a bar at its mouth, with seven or eight feet of water, and within it from two to four fathoms. The Bocca de Fiumara has only two feet of water on its bar, and consequently can be entered by nothing larger than boats. There is good anchorage at the distance of from three to six miles from the shore, where there is a depth of water of from six to thirteen fathoms, with good holding ground of stiff mud.

From the mouths of the Tiber the land continues low and marshy, and it has no town, but a few houses and towers at intervals; and, like the rest of the Campagna di Roma, of which it forms a part, is frequently so obscured by haze and fog, that the objects on the shore are not easily distinguishable. At the distance of about thirty miles from the Tiber, near a projecting headland called Cape d'Anzo, is the port and mole of Nettuno or Neptune. The mole projects 200 fathoms into the sea, and, by means of a bend towards the termination, forms a harbour, in which there is a secure anchorage, with a depth of water of from fifteen to twenty feet. The town is small, but ancient. About two miles from the mole, on the sea-shore, and around it, are several vaults, grottos, baths, and pillars, hewn out of the rocks, with other monuments of ancient magnificence. At twenty miles from Nettuno is Cape Circeo or Circello, which forms a deep bay, with a low marshy coast, near to which good anchorage, in six or seven fathoms water, is found; but there is no shelter against winds from the south-east. At ten miles from thence is Terracina, the last town of the ecclesiastical territory on the Neapolitan frontier. It was Anxur, the capital of the Volsci, in ancient times. The harbour, once of celebrity, is now choked up; and the town, though fortified, is inconsiderable. The country around is fruitful, but marshy and unwholesome.

The eastern sea-coast of the Papal States, bordering on the Adriatic Sea, extends about 120 miles in length. It commences to the south at the river Tronto (the ancient Truentus), by which it is divided from the territory of Naples, and extends to the southern mouth of the river Po, where the Austrian state of Lombardy commences. From the Tronto towards the north there are along the shore a number of small towns and villages, defended by towers, but no harbour or place of shelter, and the coast generally is low and sandy. The names of the principal places are Termoli, Vasto, Ortona, Francavilla, Pescara, and Giulianova. Next to these is the town of Fortore, where there is a great storehouse, in the form of a tower, which may be seen a long way off. To this storehouse merchandise is sent from the inland towns to be shipped; and there is good anchorage near it, with a depth of water of from six to seven fathoms, on sandy ground. About forty-five miles from the Tronto, the land trending north by west half west, is Monte Conero, or the Mountain of Ancona; but this whole line of coast is low. At seven miles north-west by north from the foot of the mountain is the mole of the city of Ancona, a surprising work, by which the harbour is formed. This mole is 2000 feet in length, 100 feet in breadth, and sixty-eight feet in height. On its point there are a battery and a lighthouse, and near it a triumphal arch of white marble, erected in honour of the Emperor Trajan, and considered as one of the most perfect remains of Roman magnificence now existing. The port has a lazaretto, where the quarantine regulations are very strict. The city is defended by a strong fort, in a low situation, on the south side. Ancona is a free port, and vessels may lie in its harbour secure from all winds, as the mole towards its termination has a turn to the west, forming a hook; it is, however, too full of shoals ever to be of consequence as a naval port. Three or four frigates may be well sheltered within the lighthouse, moored by the head and the stern; but in no part of the harbour could ships of that class swing to their anchors. The city is walled, and contains about 20,000 inhabitants. It has the best arsenal in the Roman dominions. The trade is considerable, arising chiefly from the exportation of corn, wool, and silk. The most appropriate merchant-ships for Ancona are those not drawing more than sixteen feet of water.

From Ancona to Rimini, a distance of about fifty miles, the coast is of moderate height, and the shore is of sand. The chief towns are Sinigaglia, Fano, Pesaro, and Rimini; but at none of these is there a harbour for shipping. Sinigaglia has only a mole to protect small craft; but a great fair is held here, to which many of the Greeks resort, and exchange honey, wax, tar, and other articles, for hemp, wheat, and silk. It is said to contain 10,000 inhabitants. Fano and Pesaro possess little or no trade, but are ancient places, each furnished with a great number of churches. Rimini is a small, decayed, but still elegant place, situated on the south point of the river Marecchia, near the mouth of which there is good anchorage, on muddy ground, in seven fathoms water; but there is no shelter from the sea-winds. Under the French government, Rimini was the capital of the department of the Rubicon, and contained 16,000 inhabitants. At four leagues farther to the north there is good anchorage opposite the town of Cesenatico, a place inhabited for the most part by fishermen. It is connected by a canal with the modern town of Cervia, around which there is an extensive plain, used in summer for the production of salt by natural evaporation. Upon the river Montone, about five miles distant from the sea, stands the city of Ravenna, once an important place, and the seat of government, but now fallen into decay, though still containing 16,000 inhabitants, and possessing several silk manufactories, and a considerable commerce. The river Montone is navigable for small vessels only, and its entrance is denoted by a beacon or moat, on which a light is hoisted at night. At the tower of Volano is the little port of Goro, the westernmost branch of the river Po, within which ships may enter and be secure in six fathoms water; and at four leagues from that point the Roman territory is terminated at Punta della Maestro, the outer point of the main stream of the Po. The alluvial matter of the different branches of that powerful stream has formed numerous shoals, which extend to a considerable distance from the shore, and the bank extends outwards to the distance of two leagues. Within the shoals vessels may haul up, and do so occasionally, in from six to ten fathoms water. The mouths of the Po present a figure much resembling those formed by the Mississippi in America. The river, from its source in the Alps, has a course of nearly 280 miles to the sea, and is augmented by many smaller rivers which fall into it, most of its branches being navigable by small vessels. The current is very strong, and great injury has often been done by inundations. To prevent this, strong dikes have been gradually raised on its banks, and its bed has in consequence become so elevated that the level of its waters, especially in the lower part of its course, are several feet above that of the neighbouring lands.

On the whole of the eastern coast, which has been here surveyed, there are a great number of small streams running to the sea. They have their source in the range of the Apennines, at no great distance, and are consequently of short but rapid course. Many of them are dry or nearly so in the summer, at which season the whole district suffers very severely from the want of fresh water.

The present division of the States of the Church is as follows:—

Provinces.	Extent in English Square Miles.	Population.	Cities.	Towns.	Villages.
Comarca di Roma	880	272,529	6	5	200
Legations, viz.					
Bologna	1675	306,675	2	21	371
Ferrara	1100	205,084	2	13	254
Ravenna	924	148,989	4	8	138
Forli	1232	188,097	6	9	332
Delegations, viz.					
Urbino, with Pesaro	1100	216,071	12	16	410
Ancona	550	155,397	3	17	410
Macerata, with Camerino	1474	143,820	9	17	404
Fermo, with Ascoli	1056	160,936	4	15	82
Perugia	1782	188,598	7	19	316
Spoleto	1828	148,598	6	14	204
Viterbo, with Civita Vecchia	1892	145,022	13	24	276
Frosinone	1364	117,537	7	5	200
Benevento	88	22,704	1	0	8
Velletri	660	51,500	6	7	124
	17,605	2,471,557	88	190	3729

The Marquis Vanni, who was empowered by the government in 1834 to make an enumeration, returned the population as somewhat greater, namely, as 2,592,329; and these were classed in the following manner:

Agricultural proprietors	1,176,178
Manufacturers, handicrafts, and labourers	691,805
Persons of liberal professions	24,908
Military and marine persons	21,508
Priests, monks, and nuns	53,484
Children below working age	624,446
	2,592,329

The cities containing more than 10,000 persons, with the population of each respectively, are the following:—

Rome (in 1836)	152,457	persons.
Bologna (in 1832)	69,000	...
Perugia	30,000	...
Ancona	24,000	...
Ravenna	24,000	...
Ferrara	24,000	...
Fermo	19,000	...
Faenza	18,500	...
Rimini	17,000	...
Forli	16,000	...
Macerata	15,600	...
Foligno	15,400	...
Cesana	15,000	...
Fano	15,000	...
Benevento	14,000	...
Pesaro	13,900	...
Viterbo	13,000	...
Osimo	12,300	...
Urbino	12,000	...

The population of all these cities, including that of Rome itself, does not exceed one fifth of the whole number of inhabitants. Many of the inhabitants of those cities are more or less dependent upon agriculture, and those of the smaller cities and towns are chiefly so. It may in this way be estimated, that the labour of three fourths of the inhabitants on the soil is required to produce a sufficiency of food for the whole number of consumers. The density of the population may be taken as one human being to four acres and a half of land.

According to the Marquis Vanni, the land is appropriated in the following manner:

Under the plough	242,000 rubbie.
Vineyards	14,600
Feeding land	162,000
Garden culture	1,400
Woods and forests	170,000
	590,000

The rubbia is a measure of land nearly equal to four English statute acres.

The face of the Roman territory, with the exception of those parts on the north which form part of the valley of Po, and the portion to the south on the banks of the Tiber, is hilly, and much of it mountainous. The chain of the Apennines, after forming the boundary between the Bolognese and Tuscany, enters the States of the Church near St Sepulchro, and runs through them, in the direction of north-west and south-east, at nearly an equal distance from the Mediterranean and Adriatic Seas; and then is continued through the Neapolitan provinces of the Abbruzzi, embracing in their course the valley in which the city of Rome stands. From this range of mountains spurs project on both sides, some of them extending to the Mediterranean Sea, and others to the Adriatic; and between these projections are to be found valleys of much beauty, and of the highest degree of fertility. Without any visible communication with this ridge of mountains stand the lofty elevations of the Sorriano and Fogliano in Viterbo, and the St Oreste and Monte Cavo in Frosinone. The mountains here are as naked and as desolate as those in Tuscany and in the vicinity of Genoa, but much more lofty. The highest of the Velino, to the north-west of Rome, rises 7870 feet above the level of the sea; Monte della Sibylla, on the border of the Abbruzzi, is 7058 feet; and the Somma is 6800 feet. The promontories are much lower. That of Gennaro, near Rome, is only 3924 feet, Monte Cavo 2923, and Monte Rocca di Papa only 2230 feet in height.

The summit of these mountains is composed of granite, in which are found imbedded portions of talc, gneiss, and schist. The offshoots consist in some parts of calcareous stone, and in others of volcanic tuffa, basalt, and lava. The promontories appear to be for the most part of volcanic origin, the product of that matter which seems to extend under the south of Italy. The great northern plain, which is bounded by the Apennines, the river Po, and the Adriatic Sea, has the same character as the plains of Austrian Lombardy. It is covered with a rich marshy soil, which, near Commachio, terminates in an almost useless and always insalubrious swamp. Along the south-western coast extend vast swamps, which are occasionally flooded by the sea. They are scarcely habitable, though sometimes shepherds resort to them. The pestilential volcanic air, impregnated with sulphur, causes them to be avoided. These districts, from the mouth of the river Astura to Terracina, contain the Pontine Marshes, which neither the emperors of ancient nor the popes of modern Rome have been able to render of any value. What Pope Pius VI. performed has been of no avail; and these pestiferous swamps seem to be constantly extending.

The Mediterranean Sea receives the water of but one considerable river in the Papal States. The celebrated Tiber rises in the Apennines, near St Albonigo, in the duchy of Tuscany, enters the Roman territory at the town of Sepulchro, and, taking a south-westerly direction, after a course of nearly 150 miles, and passing through Rome, falls into the sea at Ostia. It is only navigable for the last fifteen miles between the metropolis and its mouth. The tributary streams of the Tiber are the Topia and the Chiana, which originate in Tuscany, and a few small brooks and rivulets. The principal river of the Roman States is that which forms one of its boundaries, the Po. From the Roman States its water is augmented by the streams of the Panaro, the Reno, the Riolo, the Porotto, the Idice, the Santerno, the Senio, and the Lamone. These various streams are, for the most part, united by canals, and rendered navigable; and they also greatly contribute to cultivation, by affording easy means of irrigating the fields near them. Besides the Po, the other streams which empty themselves into the Adriatic from the papal territory are the following: The Montone, which runs into the sea near Ravenna; the Savio, which empties itself near Forli; the Uso, a small stream near Forli, which has become celebrated from the pope having decided, in 1756, that it was the Rubicon, though the inhabitants still maintain that the Piscatella, a small river near it, is that at which Julius Cæsar hesitated; the Matauro, which runs by Fano; the Cessano, near Urbino; the Musone, the Leta, the Asone, and the Tronto, which last forms the boundary between the Roman States and the territory of Naples.

There are several lakes in the Papal States. The largest of these is that of Perugia and Trasimeno, celebrated for the victory obtained there by Hannibal over the Romans. On the latter there are three islands. It is well stored with fish, and the outlet is into the Tiber. The lake of Bolsena is a little to the north-west of Viterbo, and was known in ancient times by the name Vulsinius. It has two islands. There is another lake near to it, that of Bracciano, which was formerly called Sabatinus. Besides these three lakes, there are many smaller, such as the charming Lago d'Albano and Lago di Remi, in the vicinity of Rome; Lago Pie di Luca, in Rieti; the lakes of Fogliana, of Monaco, of Crapolace, and Caressa, in the Pontine Marshes; and those of the valley of Commachio.

The mountainous parts of this territory abound in mineral springs of various degrees of medicinal celebrity. Those most frequented are the acid springs near Rome, the baths of Bracciano, the baths of Stigliano near Tolfa, the baths of Palazzi near Civita Vecchia, the warm baths and acid springs of Viterbo, the baths of Giosinelli near Montefiascone, the baths of Porretta in Bologna, and the Lago di Bagni, of tepid water, from which alum and sulphur are obtained, and which is much used for immersion.

The climate of the Ecclesiatical States varies much, according to the local position of the several parts. Some of those produce the orange in perfection, whilst others are covered with snow during great part of the year. The tops of the Apennines are clothed with snow in October, and it generally remains till May. The northern part, in the valley of the Po, has the climate of Lombardy, and the environs of Rome that of Sicily; whilst at Terracina the heat of the Antilles is felt, without the refreshing trade-winds. There the dates ripen, and the gardens are enclosed with fences formed by the aloe. The heat is but slightly tempered by breezes from the sea; and these parts are subject to the visitation of the dreaded sirocco. The air upon and between the Apennines is generally favourable to health; but on the Pontine Marshes, and near the mouths of the Po, as well as near to Rimini, the marshes are gradually extending, and their pestiferous influence is observable in the increase of dense fogs, and the rapid diminution of the population.

The description of the agriculture of Lombardy, given under that head in the present work, will apply to the portion of the territory of the Church near the Po, in the four delegations of Bologna, Ferrara, Ravenna, and Forli. In the other parts the art is most negligently exercised, as well in the Apennines as in the plains of Rome itself. The Roman States produce a sufficiency of corn for their own consumption; for if some districts are deficient, the others are more than sufficient. Wheat, maize, and barley, are the chief grain; but the great mass of the poorer people eat but little bread, and, especially in the Apennines, substitute chestnuts, onions, garlic, and beans instead of it. A great part of their food consists of fruits, culinary vegetables, and salads. They rarely taste animal food, except a little bacon or sausages. Flax and hemp are raised in sufficient quantities to supply the inhabitants; and saffron is produced to such an extent that it has become an article of export. Some cotton is raised, and the growth of it is rapidly extending. In some parts many plants are raised that are applied by the perfumers to their preparations, such as spikenard, annis, and others. The olive grows everywhere, but is almost exclusively destined to domestic consumption.

Wine is generally cultivated, but the management of the vines is careless, and the selection of the kinds of them very negligent and injudicious. The best wine is made about Montefiascone, Orvieto, and Monte Cavo; but the greater part of the common wine is very indifferent. Some little of a moderate quality is made about Bologna and Ravenna, part of which finds a market in Venice. The land produces a great variety of fruits. In the plain of Rome, oranges, citrons, pomegranates, and figs ripen; and amongst the Apennines there is an abundance of almonds, pistachio-nuts, and walnuts, and especially of chestnuts. The forests produce wood for fuel, and some little is sent to the Isle of Elba to supply the iron-works. On several parts of the coast much soda is prepared. The woods of Terracina have many cork-trees, the bark of which becomes an article of foreign commerce.

Formerly the breeding of horses was carefully attended to, but of late it has been negligently pursued; and the celebrated race known by the name of Borghese has deteriorated, and nearly disappeared. On the Apennines asses and mules are used as beasts of burden, for riding, and for the plough. Oxen are almost universally employed. The breed of cows is very fine; and they roam about the Campagna di Roma almost without attendance. The milk is not converted into cheese or butter, but the profit they yield to the proprietors, some of whom have herds of nearly two thousand, arises from the sale of the calves, and of the mothers when fattened. Sheep are very numerous, especially on the shores of the Mediterranean. There are two distinct races. One of these, called *negretti*, are small, with very strong and very white wool, as fine as that of Aragon, whence the race, as well as the name they bear, has been derived. They give abundance of milk, from which much cheese is made. These flocks, like their ancestors in Spain, are migratory. In the month of May they march from the plains near Rome to the mountains of Norcia and Abbruzzi, and return again in October. The other race of sheep, called *pouille*, are inferior in their wool, and are stationary on the Apennines, and the lands situated on the Adriatic shore. Goats are very numerous, both on the plains and on the Apennines. They yield abundance of milk, which is converted into cheese; but much of it serves to sustain the swine, of which large herds are bred and fattened upon some of the most extensive farms. The culture of silk is one of the most important objects in Roman agriculture, and gives occupation to almost every member of certain families for the season. The soil is favourable to the growth of the white mulberry, the leaves of which yield the finest silk; that of the best quality, collected near Fossombrone, is chiefly exported to England and Germany.

The manufacturing operations of the Ecclesiastical States are very confined, and chiefly adapted to domestic consumption. The chief seat of the silk manufactory is Bologna, which formerly had the monopoly of the trade in crapes, but now divides it with the fabrics of other parts of Europe. Linen and woollen cloths are made, some good paper is produced, and leather is made in several parts; also glass, pottery, rosaries from Loretto, artificial flowers, tallow, and wax-candles, with a variety of small articles.

There are no mines worked within the Roman territory, but considerable quantities of excellent alum and of sulphur are furnished, and some saltpetre; and on the coast there are lagunes, from which culinary salt is made by the natural evaporation of the sun's rays.

The subjects of the Roman pontiff all adhere to the Catholic church, with the exception of 16,000 Jews. The states have six archbishops, seventy-two bishops, 1824 religious houses for monks, and 612 nunneries, and 2098 parochial divisions. The civil government is in the hands of the college of cardinals, and the executive is administered by the Cardinal Vicarius, who is a kind of prime minister. The universities in actual operation are but three, viz. Bologna, with 680 students; Rome, with 460; and Perugia, with 200. Besides these, four others have been decreed in Camerino, Fermo, Macerata, and Ferrara, but are not as yet established. In most of the cities there are schools of the fine arts, which tend to keep alive the attachment to music, painting, statuary, and antiquities, for which, with architecture, Italy has long been celebrated. The education of the poorer classes is less attended to than in some other parts of Europe.

The military force of the Holy See, as regulated by a decree of the 29th of December 1834, consists of ten battalions of native and two of foreign infantry, one regiment of dragoons, one of carabineers, two of sharp-shooters or riflemen, and a corps of artillery, the whole amounting to 17,372 men, and 1524 horses. There is at present no marine force of any description.

The finances of the Roman States are not clearly known.

The public debt is calculated to exceed eight millions sterling, and to be annually increasing, although the taxes levied are said to be heavier in proportion to the wealth of the community than they are in any of the other European states. (G.)

PAP CASTLE, in England, in Bridekirk parish, Cumberland, originally stood two miles from Cockermouth, on the other side of the Derwent. Its antiquity is proved by several monuments; and a large green stone vessel found here, with little images upon it, is supposed to have been formerly a Danish font. Pap Castle, which seems to have been so called from Pipard, its owner, is said to have been demolished, and the materials employed in building Cockermouth Castle.

PAPEMBERG, a high island off the coast of Japan, called by the natives Takaboko, or Takajama.

PAPER.

PAPER is a word derived from the Greek πάπυρος, *papyrus*, the name applied to the celebrated Egyptian plant which was so much used by the ancients in all kinds of writing. It is unnecessary to describe the different expedients which men have in every age and country employed for giving permanence to their ideas, and handing them down to posterity. When the art of writing was once discovered, stones, bricks, leaves of trees, the outer and inner bark, plates of lead, wood, wax, and ivory, were all employed. In the progress of society, men have invented the Egyptian paper, paper made of cotton, paper manufactured from the bark of trees, and in our times paper prepared from old rags.

The only kinds of paper which merit particular attention are, first, the Egyptian; secondly, that made from cotton; thirdly, paper made from the interior bark of trees; fourthly, Chinese paper; fifthly, Japanese paper; sixthly, paper made from asbestos; and, lastly, paper prepared from linen and cotton rags.

Egyptian paper.

Egyptian paper is that particular kind which was used by the ancients, having been made from a kind of reed called *papyrus*, which grew on the banks of the Nile. Isidorus is of opinion that this paper was first used at Memphis, and Lucan (*Pharsalia*, lib. iii. ver. 222), speaking of a particular period, says,

> Nondum flamineas Memphis connexere biblos
> Noverat.

But however this may be, it is certain, that of all the kinds of paper used by the ancients, the papyrus was the most convenient, both from its flexibility, and from the ease with which it was fabricated. In fact it seemed a present from nature, and required neither care nor culture. It is not certain at what particular period the ancients began to make paper of papyrus; but there are several authorities which prove that it was prepared in Egypt long before the time of Alexander the Great.

Pliny (lib. xiii. cap. 11) gives a very full description of the method of making this paper in Egypt. According to him, they divided, with a kind of needle, the stem of the papyrus into thin plates or slender pellicles, each of them as large as the plant would admit. These were the elements of which the sheets of paper were composed. The pellicles in the centre were the best; and they diminished in value as they receded from it. When these pellicles were separated from the reed, they were extended on a table, and laid across each other at right angles, in which state they were moistened by the water of the Nile, and whilst wet were put under a press, and afterwards exposed to the rays of the sun. It was supposed that the water of the Nile had a gummy quality necessary to glue these stripes together. But, according to Bruce, we may be assured that this is without foundation, no such quality being discovered in the water of the Nile; on the contrary, he found it of all others the most improper, till it had settled and become absolutely divested of all the earthy particles collected in its turbid state. He made several pieces of this paper both in Abyssinia and Egypt; and it appeared to him that the saccharine matter with which the whole juice of the plant was impregnated was that which caused the adhesion of these stripes together, and that the only use of the water was to dissolve this matter, and bring it into perfect and equal fusion. When there was not enough of sugar in the plant, or when the water did not sufficiently dissolve it, the pellicles were united by a paste made of the finest wheat flour, mixed with hot water and a little vinegar; and when dried they were flattened and smoothed by means of a mallet.

The size of this paper varied much; yet it seldom exceeded two feet, and was often smaller. It had different names, according to its size and quality. The first, called *imperial*, was of the finest and largest kind, and used for writing letters by the great men amongst the Romans. The second, called the *Livian* paper, from Livia the wife of Augustus, was next to the imperial, and in size twelve inches. The third sort, called the *sacerdotal* paper, was eleven inches in size. The paper used in the amphitheatres was of the dimensions of nine inches; but it was esteemed on account of its strength, whiteness, and polish. The ink, however, sunk less in paper highly polished, and therefore the characters were more liable to be effaced. When it was not carefully soaked in the first preparation, the paper brought a less price, because letters were with difficulty formed upon it, and it emitted a disagreeable odour. To remedy this defect, the paper went through a new course of sizing and hammering; and the size employed on the occasion was made of light bread steeped in boiling water, and passed through a filtering cloth. By this means the paper became in the highest degree united, and smoother than the finest linen.

It was this paper which gave so long a duration to the works of the Gracchi in their own handwriting. "I have seen them," says Pliny, "in the library of Pomponius Secundus, a poet and citizen of the first rank, nearly two hundred years after they were written." It may be added, that there still remain manuscripts of this paper, which were undoubtedly written a thousand or twelve hundred years ago. It appears from Pliny, that the Egyptians pasted together the pellicles of the papyrus by means of the waters of the Nile; but that the polishing with ivory, and the operations of the hammer and the press, were added by the invention and industry of the Roman artists. The Egyptians seem to have known the use of size; but it is evident from the same author that the Romans used a stronger size in the making of paper. Notwithstanding the care which was taken to give strength and consistency to the Egyptian paper, the leaves, although collected into a book, were too weak to support themselves; and for this reason it was a very common practice to insert a leaf of parchment after every five leaves.

This paper formed an important branch of Egyptian commerce, which continued to increase towards the end of the Roman republic, and became still more extensive in the reign of Augustus. The demand from foreign nations was often so great as to occasion a scarcity at Rome; and in the reign of Tiberius a tumult occurred amongst the people in consequence of this scarcity. In a letter of the Emperor Hadrian, the preparing of papyrus is mentioned as one of the principal occupations at Alexandria. "In this rich and opulent city," says the emperor, "nobody is seen idle. Some are employed in the manufacture of cloth, some in that of writing paper." During the time of the Antonines, this commerce continued to flourish; and Apuleius says that he wrote upon the paper of Egypt with a reed of the Nile prepared at Memphis.

Towards the end of the third century, the demand for this paper became so great, that when the tyrant Firmus conquered Egypt, he boasted that he had seized as much paper and size as would support his whole army. St Jerome informs us that it was much in use in the fifth century, when he flourished. The duty on the importation of this commodity had become excessive towards the end of the fifth or the beginning of the sixth century; and this duty having been abolished by Theodoric king of Italy, Cassiodorus congratulates the whole world on the discharge of an impost on a merchandise which was so essentially necessary to mankind.

Montfaucon and Mabillon mention several fragments written on this paper in the sixth centry. One of these was a charter of the Emperor Justinian, entitled *Charta Plenariæ Securitatis*. In 1698, Montfaucon saw, in the library of Julio Justiniani, three or four fragments of Egyptian paper of the same antiquity; and Mabillon mentions some books of the Jewish Antiquities of Josephus translated into Latin, which seemed to have been written in the same century, and which were preserved in the Ambrosian Library at Milan; but he had not seen the manuscripts. The same antiquary mentions having seen in the library of St Martin of Tours the remains of an old Greek manuscript of Egyptian paper, and which appeared to him to be of the seventh century. He also believes that the copy of St Mark's gospel preserved in the register-house of Venice is written upon the same paper; that it is the most ancient of any of the evangelical manuscripts; and that it may be supposed to have been written at the latest in the fourth century. According to the same antiquary, the Egyptian paper was used in France, Italy, and other European countries, both for books of learning and for public records; and there still remains, he adds, a great number of these in the archives of the church at St Denis, at Corby, in the Abbey de Grasse, and in other convents.

It is probable that the invention of paper made of cotton, of which we shall afterwards treat, insensibly destroyed the reputation and manufacture of the Egyptian paper; but it is still a question at what particular period the fabrication of the latter totally ceased. Eustathius, the learned commentator on Homer, assures us that in his time it was no longer in use; but Mabillon maintains that many of the papal bulls were written on papyrus in the eleventh century. Count Maffei, however (*Histor. Diplomat.* lib. ii.; *Biblioth. Ital.* tom. ii. p. 251), is decidedly of opinion that Egyptian paper was not in use in the fifth century. He considers all records written upon this paper, and dated subsequently to this period, as not authentic; and the papal bulls mentioned by Mabillon, as well as the copy of St Mark's gospel, were, according to him, written upon paper manufactured from cotton. To reconcile in some measure these contradictory accounts, it may be observed, that on some particular occasions, and by some particular persons, the Egyptian paper might have been employed for several hundred years after it ceased to be in general use.[1]

Paper made from cotton.

It is generally supposed that the invention of the paper called *charta bombycina* supplanted the Egyptian paper in Greece. This paper is incomparably more lasting, and better calculated for all the purposes of writing. It is not precisely known at what period this art, which supposes a great variety of previous experiments, was first reduced to practice. The application of cotton to the purposes of paper-making requires as much labour and ingenuity as the use of linen rags; and for this reason, if we would determine the precise time when paper was made from cotton, we should also be able to fix the invention of the art of paper-making as it is presently practised in Europe. Montfaucon proves, by incontestible authorities, that paper made from cotton was in use in 1100. This paper in the Greek language is called χαρτη βομϐυκινος, or βαμϐακινος; for although βομϐυξ is the Greek word for silk, yet in those times it was applied, as well as βαμϐαξ, to cotton; and hence the Italians call cotton *bambaccio*.

The most ancient manuscript of this paper which Montfaucon saw with a date, was that in the French king's library, written in the year 1050; but as the manuscripts without date are infinitely more numerous than those which are dated, and as some conjecture can be formed concerning them from the manner of the writing, the same antiquary believes that some of these were written in the tenth century. The researches of the same learned person serve to show that this paper was discovered towards the end of the ninth or beginning of the tenth century; for before the twelfth century it was commonly used throughout the eastern empire, and even in Sicily. Roger king of Sicily says, in a diploma written in 1145, that he had renewed on parchment a charter which had been written upon cotton paper in the year 1100, and another which was dated in the year 1112. About the same time the Empress Irene, in the statutes for regulating some religious houses at Constantinople, states that she had left three copies of these statutes, two on parchment, and one on cotton paper. From that period paper of this sort became still more in use throughout all the eastern empire; and innumerable Greek manuscripts are found written upon it, in all the great libraries.

This discovery happened at a time when there seems to have been a great scarcity of parchment; for it was about the same period that the Greeks erased the writings of Polybius, Diodorus of Sicily, and many valuable ancient authors, for the sake of the parchment. It was the invention of this cotton paper which destroyed the manufacture of the Egyptian article; for, if we may believe Eustathius, who wrote towards the end of the twelfth century, the latter had gone into disuse but a little before his time. We may easily believe, however, that this new invention, although of great advantage to mankind, was only introduced by degrees.

Paper from the bark of trees.

Paper of the interior bark of trees was made from the white pellicle or inner coat which is found in many trees between the bark and the wood. The trees commonly in use were the maple, the plane-tree, the elm, the beech, the mulberry, and most commonly the linden-tree. The ancients wrote upon this inner coat after they had separated it from the bark, and beaten and dried it. Mabillon and Montfaucon speak frequently of manuscripts and diplomas written upon paper made from bark; and positively distinguish it from the Egyptian paper, because it was thicker, and composed of parts less adhesive.

There are many palm-trees in India and America to which botanists have given the name *papyraceous*, because the natives have written with bodkins either on the leaves or on the bark. Such is the American palm, called *tal* by the Indians; and also the *guajaraba* of New Spain. Every palm, the bark of which is smooth, and the leaves large and thick, may be used for this purpose.

---

[1] Whoever wishes for a fuller account of the Egyptian paper, may consult, amongst the ancients, Pliny (lib. xiii.), and Theophrastus (lib. iv. chap ix.); and amongst the moderns, Guilandinus, Scaliger, Saumaise, Kerchmayer, Nigrisoli, Hardouin in his edition of Pliny, Mabillon in his work *De Re Diplomatica*, Montfaucon in his Paleography and Collections; Maffei in his *Histor. Diplomat.*, Count de Caylus in the Memoirs of the Academy of Inscriptions, and Bruce in his Travels to discover the Source of the Nile.

Chinese paper.

The art of making paper from vegetable matter reduced to pulp was known in China long before it was practised in Europe; and the Chinese have carried it to a high degree of perfection. The fine paper of China is much softer and smoother than that of Europe; and these qualities are admirably adapted to the pencil, which the Chinese use in writing. Several kinds of their paper discover the greatest art and ingenuity, and are applied with much advantage to many purposes. These are capable of receiving the impression of types; and Chinese paper is celebrated for affording the most clear and delicate proof-impressions from copperplates.

The different sorts of paper vary in China according to the materials of which they are composed, and the various modes of manufacturing these materials. Every province has its peculiar paper. That of Sechuen is made of linen rags, as in Europe; that of Fo-kien, of young bamboo; that of the northern provinces, of the interior bark of the mulberry; that of the province of Kiang-nan, of the skin which is found in the webs of the silk-worm; and in the province of Houquang, the tree chu or ko-chu furnishes the materials of which paper is made.

The method of fabricating paper from the bark of different trees is nearly the same with that which is followed in the bamboo. To give an idea, therefore, of the manner of manufacturing the interior barks of the mulberry, the elm, and the cotton-tree, it will be sufficient to confine our observations to the bamboo.

The bamboo is a kind of cane or hollow reed, divided by knots, but larger, more elastic, and more durable, than any other reed. The whole substance of the bamboo, composed of filaments, and a great abundance of fibrous materials, are employed in this operation. The shoots of one or two years, nearly as thick as a man's leg, are preferred. They strip the leaves from the stem, cut them into pieces of four or five feet in length, make them into parcels, and put them into water to macerate. As soon as they are softened, which generally happens in five days, they are washed in pure water, put into a dry ditch, and covered for some days with lime watered for the purpose of slacking. They are then washed carefully a second time, and every one of the pieces is cut into filaments, which are exposed to the rays of the sun to dry and to bleach. After this they are boiled in large kettles, and then reduced to pulp in mortars of wood, by means of a hammer with a long handle, which the workman moves with his foot.

The pulp being so far prepared, some shoots of a plant named *koteng* are taken, and being steeped in water four or five days, are reduced to an unctuous or glutinous substance; and when the workmen proceed to make the paper, this is mixed with the pulp in certain fixed quantities, because upon this mixture depends the quality of the paper. When the extract from the koteng is mixed with pulp of the bamboo, the whole mixture is beaten together in mortars till it become a thick and viscous liquor; when it is poured into large tubs or reservoirs, so exactly framed as that no part of the liquor can escape. After this the workmen plunge their forms into the liquor, and take out what is sufficient for a sheet of paper, which, when formed and consolidated, is at once dried and detached from the mould, by being held a moment or two against a heated hollow wall, the two fronts of which are smooth and extremely white. At the extremity of this wall is placed a stove, the pipes of which are carried in a circular manner throughout the whole empty space. The sheets of paper are laid on the surface, to which they adhere till a soft brush is applied to them; and after they become dry, it is easy to distinguish the side which received impressions from the brush from that which adhered to the wall. By means of this stove the Chinese dry their paper as fast as they make it; but it is only in cold seasons, or in certain provinces, that they find this expedient necessary.

The Chinese paper must be dipped in a solution of alum before it can take either ink or colours. They call this operation *faner*, from the Chinese word *fan*, which signifies alum. The manner of preparing this solution is extremely simple. Six ounces of isinglass cut very small are put into boiling water, and constantly stirred, that it may dissolve equally. When the isinglass is wholly dissolved in the water, twelve ounces of calcined alum are thrown in, and also stirred till it is completely dissolved and mixed with the isinglass. This composition is afterwards poured into a large deep bason, at the mouth of which there is a little round piece of wood; and the extremity of every sheet of paper is then fixed in another piece of wood, with a slit made to receive it. By means of this apparatus the sheet of paper is plunged into the composition of alum and isinglass; and when it is fully penetrated by the mixture, it is drawn out, and made to glide over a little round piece of wood. The long piece of wood which holds the sheet by one end, and keeps it from tearing, is afterwards suspended with it on a wall till it becomes sufficiently dry.

The Chinese give to the paper intended for different purposes different colours; but we shall confine our observations to the silver colour, which they impart to some kinds. They take two scruples of paste made of cow's hide, one scruple of alum, and a pint of water, and boil the whole on a slow fire till the water be evaporated. The sheets of paper are then stretched on a smooth table, and covered over with two or three layers of this paste. They afterwards take a certain quantity of talc, washed and boiled in water, with a proportion of one third of alum. The whole is then dried, reduced to a powder, passed through a sieve, boiled a second time in water, dried in the sun, and again passed through the sieve. This powder is then spread equally over the sheets of paper, prepared as above mentioned; and these are afterwards dried slowly in the shade. The sheets of paper, covered in this manner with talc, are laid upon a table, and rubbed with a little cotton, which fixes a certain quantity of talc in the paper, and carries off the surplus to be used on another occasion. By means of this composition the Chinese draw all manner of figures on their paper.

The paper made from the bamboo is sufficiently white, soft, and closely united, without the least inequality on the surface to interrupt the motion of the pencil, or to occasion the rising of the materials which compose it. But every kind of paper made from the bamboo or the bark of trees is more liable to crack than that made in Europe; besides, it is more susceptible of moisture, and is sooner destroyed with dust and worms. To obviate this last inconvenience, people are obliged frequently to beat their books in China, and to expose them to the sun. It may be observed, however, that the Chinese paper, employed for various purposes in Europe, has been preserved for a long time without receiving damage either from moisture or from insects.

Japanese paper.

According to Kæmpfer, the bark of the *morus papifera sativa*, or true paper-tree, is chiefly employed for making paper in Japan. Every year, after the fall of the leaves, which happens in the tenth month, corresponding to our December, the Japanese cut the young shoots of this tree into pieces of about three feet, and collect them into parcels, which they boil in water containing a certain quantity of ashes. If the wood be dry, they take care to steep it twenty-three hours in water before it is boiled. The parcels are kept in a close copper till the bark at the extremity of the shoots is separated from the stem about half an inch; they are then cooled, and the bark alone is fit for making paper. They begin by a preparation, which consists of cleaning the bark, and separating the good from what is bad. For this purpose they steep it in water three or four hours; and as soon as it is softened they scrape off with a knife whatever is blackish or green, and at the same time separate the strong bark of a year's growth from the slender kind which covers the young shoots. The first of these gives the whitest and best paper. If there be any of the bark of more than a year's growth, it is laid aside for the coarsest kind.

After the bark has been culled and cleaned in this manner, it is boiled in a clear ley till the matter is of such consistency, that, being gently touched with the finger, it draws off in the form of hairs, or like a collection of fibres. During the time of boiling it is constantly stirred with a strong reed, and the waste by evaporation is supplied from time to time with additional quantities of the clear ley. To make this ley, they put two pieces of wood across the mouth of a tub, and cover them with straw, upon which is laid a bed of ashes a little moistened; and when boiling water is poured on the ashes, the salts contained in them are carried down to the tub. This is what is called a *clear ley*. After the bark is in the condition which we have just stated, it is washed with great care; for on this washing depends in a great measure the quality of the paper. It is put into a kind of sieve through which the water can flow freely; and great care is taken to turn it with the hand till it be sufficiently diluted, and reduced to soft and tender fibres. For the finest paper a second washing is requisite, and a piece of cloth is used instead of a sieve.

When the bark is washed, it is laid upon a strong and smooth table, and beaten with a kind of baton of hard wood till it is reduced to a proper consistency. Indeed it becomes so soft that it resembles paper steeped in water. The bark prepared in this manner is put into a narrow tub, with a glutinous extract from rice and the root *oreni*, which is very viscous. These three substances are mixed together, and stirred with the reed till they form a liquor of uniform consistency. The composition is then poured into vats similar to those used for filling the forms or moulds in our paper-mills.

As soon as the sheets are made and detached from the form, they are laid in a heap upon a table covered with a double mat. A small chip of cane is placed between every sheet, and this jutting out serves to distinguish the sheets, and afterwards to raise them. Every one of the heaps is covered with a plate or thin board of the exact size of the paper. In proportion as the paper dries, or is able to bear it without danger of being compressed into one mass, they lay on additional weights. This pressure, being intended to carry off any unnecessary moisture, is continued during twenty-four hours, when the sheets are, by means of the little pieces of reed, suspended to long plants in the open air, till they are completely dried.

The extract from rice is made in an unvarnished earthen pot, which is at first agitated gently, and then more briskly; new water is next poured in, and the whole is filtered through a linen cloth. The finishing of the process is determined by the viscosity of the substance. The infusion of the root *oreni* is prepared in this manner: The root, peeled and cut into small pieces, is infused in water for one night, during which time it communicates a viscosity sufficient for the purpose to which it is applied.

The Japanese paper is of such prodigious strength, that the materials of which it is composed might be manufactured into ropes. There is sold at Serige, the capital city of the province of that name, a kind of paper which is fit for bed-hangings and wearing apparel, and so much resembles stuffs of wool and silk that it is often taken for them. There are four trees used in Japan for the manufactory of paper:—1. The true paper-tree, called in the Japanese language *kaadsi*, and characterized by Kæmpfer as *papyrus fructu mori celsæ, sive morus sativa foliis urticæ mortuæ cortice papifero:* 2. The false paper-tree, called by the Japanese *katsi* or *kadsire*, and by Kæmpfer *papyrus procumbens lactescens folio longo lanceata cortice chartaceo:* 3. The plant which the Japanese call *oreni*, and which is named by Kæmpfer *malva radice viscosa flore ephemero magno punico:* 4. The *futokadsura*, named by Kæmpfer *frutex viscosus procumbens folio telephii vulgaris emulo fructu racemoso.* The description of these trees, as given by Kæmpfer, may be of service in leading botanists to discover the European plants and shrubs adapted, like the Japanese, for the fabrication of paper.

Before concluding this part of the subject, it may be proper to give an idea of the attempts which have been made to increase the original materials of paper in Europe. A slight attention to the Chinese process in reducing the bamboo to a paste, by a careful and ingenious analysis, and to the method employed by the Japanese in separating the principal fibres of the bark of the mulberry, will show the absurdity not only of taking plants without any kind of choice, but of giving them no preparation, except that of pounding them with mallets. With a proper selection and right treatment, it appears probable that many of the European plants might be used with great advantage in fabricating several kinds of paper. It is evident that the materials used by the Chinese require less labour and preparation than the stuff of linen rags. The sheets of the Chinese paper are easily detached from the form; they are laid in heaps, without the interposition of pieces of woollen cloth; the superfluous water is immediately discharged; and they require not, as in Europe, the vigorous action of presses to unite the parts more closely together.

Paper made from asbestos.

Asbestos is a fibrous substance of little strength, and the threads of which are easily broken. This substance has the peculiar property of supporting the action of fire without receiving any damage; and hence pieces of cloth and garters made of it are incombustible. From the knowledge of this property, paper has been made of asbestos. The manner of fabricating this paper is described by Mr Lloyd in the *Philosophical Transactions* (No. 166). A certain quantity of asbestos is pounded in a stone mortar till it be reduced to a substance like cotton. All the parts of earth or stone remaining in the asbestos are then taken off by means of a fine sieve, and it is formed into sheets of paper by an ordinary paper-mill. Mixing it with water reduces it to stuff; but as it is heavier than that made from linen rags, it requires to be continually stirred when it is taken up with the frames. The only excellence of this paper is, that the writing disappears when cast into the fire. But as it is of a slender consistency, and easily torn, it is rather an object of curiosity than of use.

Paper made from rags.

This paper is manufactured throughout all Europe, in the East Indies, and in America, from linen and cotton rags collected in the cities and in the country. Paper made of linen rags was utterly unknown to the ancients. The *libri lintei* mentioned by Livy (i. lib. iv.), Pliny (lib. xiii. c. xi.), and other Roman writers, are demonstrated by Guilandin, in his commentary on Pliny, to have been written on pieces of linen cloth, or canvass prepared in the manner of painters. But it is not sufficient to be certain that paper made from linen is a modern invention; it is necessary to know by what nation, and at what period, it was discovered. Polydore Virgil (*De Inventoribus Rerum*, c. ii. c. viii.) confesses his ignorance of this circumstance. Scaliger, without any kind of proof, gives the credit of the invention to the Germans; and Maffei claims it for the Italians. Other writers ascribe this honour to some Greek refugees at

Basil, to whom the manner of making paper from cotton in their own country had suggested the idea. Duhalde is persuaded that Europe derived this invention from the Chinese, who, in several provinces, make paper of rags nearly in the same manner as we now do. But this invention was practised by the Europeans before they had any communication with China, and before the taking of Constantinople, at which time the Greek refugees were supposed to have retired to Basil. The precise date of this discovery in Europe is not exactly known. Mabillon believes that it took place in the twelfth century, and cites a passage of Pierre de Clugny, born in the year 1100, to prove it. The books which we read every day, says De Clugny, in his treatise against the Jews, are written on sheeps' and calves' skins, or on oriental plants, or, finally, *ex rasuris veterum pannorum*. If these last words signify paper such as we use, there were books of it in the twelfth century. But this citation is the more to be suspected, as Montfaucon himself, after the minutest search in France and Italy, could find no book on this paper anterior to the death of St Louis, in the year 1270.

The epoch of this invention was not approximately determined till 1762, when M. Mierman proposed a reward to the person who could procure the most ancient manuscript written on this kind of paper. The collection of all the memoirs sent to him, along with the manuscripts, was published at the Hague in 1767; and it appeared that this paper had been used in Europe before the year 1300.

In 1782 the Abbate Andrez published a work, entitled *Dell' Origine, Progressi, e Stato attuale d'ogni Letteratura*, in which he speaks of the discovery of many kinds of paper, and particularly of that made of rags. The same person maintains, that paper made from silk was very anciently fabricated in China, and in the eastern parts of Asia; and that the art of making this paper was brought from China to Persia about the year 652, and to Mecca in 706. The Arabs substituted cotton, the commodity of their own country, instead of silk, or rather of bamboo. This cotton paper was carried into Africa and Spain by the Arabs. The Spaniards, from the quantity of linen to be found in the kingdom of Valencia, seem first to have adopted the idea of using linen rags; and hence the most ancient paper of this kind is that of Valencia and Catalonia. From Spain it passed into France, as may be gathered from a letter of Joinville to St Louis about the year 1260; and it is discovered to have been made in Germany in 1312. The first paper-mill in England was erected at Dartford by a German named Spielman in 1588, who was knighted by Queen Elizabeth. In consequence of paper made from cotton being imported from the Levant, paper made from linen was introduced much later into Italy, than into France, Germany, and England.[1]

Art of paper-making in Europe.

This manufacture owes, in a great degree, the prodigious advancement which it has attained in Great Britain during the last thirty years, to the ingenious and successful application of machinery. Many of its formerly tedious and uncertain processes are thereby greatly simplified and abridged; a remarkable instance of which is the improvement of cylinder-drying. The drying process used formerly to be effected mainly by the agency of the atmosphere; but since the paper-machine was perfected, the paper is now made to pass in the web, as it is formed, over the surface of a certain number of metal cylinders heated internally by steam, and is dried off in less than two minutes, whereas it was formerly exposed in the winter season to the frequent occurrence of being for weeks or months kept in a damp state, or exposed to severe frost, to its certain and great damage.

The manufacture naturally divides itself into that which is carried on in *hand-mills*, where the formation of the sheet, as formerly, is still performed by manual labour; and that which is carried on by *machine-mills*, where the paper is formed upon the machine wire-cloth in one continuous web. To give a distinct view of the subject, it will be necessary to describe all the important parts of the operation in their order, most of which are common to both modes of manufacture.

Materials.

The materials principally used in Great Britain are old linen and cotton rags, which are collected in great quantity at home. A large quantity of rags, chiefly linen, is annually imported from the different countries whence the exportation is not prohibited, viz. Germany, Italy, Sicily, and Hungary. Within the last ten years a very abundant supply of material, formerly considered as totally worthless, has been obtained from the cotton factories in Manchester and its neighbourhood; we allude to the cotton waste, and sweepings of the cotton-mills, which, by being *devilled*, that is, cleaned by a machine used in the cotton manufacture called a devil or skreening machine, and afterwards boiled in alkaline solution, and bleached, are capable of being converted into very tolerable printing paper.

The selection of the rags, if it should not have been performed before they are brought to the paper-mill, is there performed by women sorting them into their various qualities, which facilitates the work of the rag-cutters, whose business it also is to sort the rags into their different kinds as they cut them. The rags are then assigned, in bags or bales of from two to five hundredweights each, to the women in the rag-house. These women stand at small tables of about three feet square, the upper surface being composed of iron wire cloth, the meshes of which are about one fourth of an inch square, whilst underneath there is a drawer. A knife or short scythe is firmly fixed in the centre of the table, in nearly a vertical position, and the woman is placed so as to have the back of it standing next her, and with a large wooden box divided into several compartments upon the floor, on her right hand. She then opens and examines the seams and patches of the rags, and removes the dirt, as well as any other noxious substances, such as pins, needles, buttons, silk and worsted pieces, &c. that may be attached, which would be hurtful to the machinery, as well as to the quality of the paper. She cuts the rags, by drawing them to her across the edge of the scythe, into pieces not exceeding four inches square, which are sorted and thrown into the boxes above referred to, according to their different qualities. A great deal of the dirt, sand, &c. passes through the wire-cloth into the drawer of the table, which is opened and cleaned out at convenience.

The rags, after being thus cut and sorted, are again carefully examined by women called *overlookers* or *overhaulers*, who have the charge of seeing that the work is properly performed, and that none of the noxious substances above referred to are allowed to remain in the rags. Much of the beauty and cleanliness of the paper, when finished, depend upon due attention being insisted upon in this department; for any dirty or noxious substances, when once comminuted by the trituration of the *stuff* into an endless number of small particles scattered over the surface of the paper, are of course wholly fixed and irremoveable.

Several machines have of late years been invented for the purpose of cutting rags, and thereby abridging the labour and expense. By means of rollers they are carried round a large cylindrical drum, on which knives, placed diagonally, revolve with considerable velocity and power, and cut the rags into small diamond-shaped pieces. But such machines have hitherto been found of comparatively little service, as of course they cannot perform the work of selection, or the removal of the impurities from the material, which can only be done by careful and close examination at the time of cutting the rags, and with the advantage of using the sharp knife to cut or scrape off the injurious portion. These rag-cutting machines, moreover, have been apt to cut the rags into very unequal sizes, leaving one portion much too large, and another portion much too reduced, for the due trituration of them afterwards.

---

[1] See the work of Abbate Andrez, printed at Parma, 1782, in 8vo; and Mierman's Collection, published at the Hague.

After the rags have been cut and carefully examined, they are enclosed in a cylinder called a duster, the whole circumference of which is composed of iron wire cloth; it measures about four feet and a half in diameter, and is about five feet in length; and a part of the circumference opens on hinges to admit the rags, from one to two hundredweights of which are generally enclosed at a time, and remain in motion for half an hour or an hour. On the axis in the interior of the cylinder there are a number of spokes, each about one foot long, fixed transversely, which pass through the rags when they are in rapid motion, and toss them about so as to make them part the more readily with the dust, sand, and dirt, which may still adhere to them. For the coarser and dirtier descriptions of rags this machine is used with good effect before they are cut, and renders the operation of cutting the rags less accompanied with dust, &c., and therefore less unpleasant and unwholesome to those engaged in it.

The women engaged in the rag-house cut on an average about three quarters of a hundredweight of home rags, that is, rags collected in Scotland and England, in the day of ten working hours, and about one hundredweight and a half of foreign rags in the same time. This arises from the latter being of a much heavier and stronger substance, generally speaking, than the former. Their wages amount to from tenpence to a shilling per day on an average. The nature of their employment, though it subjects them to the inhalation of dust and fibrous matter floating through the air, does not seem at all to injure their health, nor to warrant the adoption of what medical men have sometimes volunteered to recommend, that of breathing through sponges placed over their nose and mouth, to prevent injury to their chests and lungs.

The next process is that of boiling the rags in an alkaline ley, which is rendered proportionally strong, according to the lowness of the quality of the rags and the quantity of the colouring matter to be discharged. In some mills large open-mouthed coppers, with fire under them, are used for this purpose; in others, where there is a full command of steam, the rags are boiled in large square iron boxes, capable of containing ten or twelve hundredweights at a time. Part of the lid is made to move on hinges, or with a rope and pulley and balance-weight, for the purpose of the rags being placed in and taken out of the vessel; and before the steam is allowed to pass into the chest, the lid is secured by being screwed tightly down, and the joints of it formed by oakum to prevent the blowing of the steam. The steam passes through an upright iron pipe of about an inch and a half in diameter, through the centre of the lid down to the bottom of the chest, whence it diverges through a number of pipes or radii towards the sides of the chest. There is a false bottom, also of iron, which is in moveable pieces, about six inches above the real bottom; it is perforated by a number of small holes, to allow the boiling ley to pass constantly through the mass.[1]

The quantity of alkaline matter varies from four to ten pounds of carbonate of soda to each hundredweight of rags, according to their quality, with about one third part additional of quicklime, to render the ley caustic. The boiling is carried on upon an average for about eight hours, after which the rags are cooled as gradually as possible, since the process of cooling, if rapidly carried on, tends to fix some of the black colouring matter again in the rags. Some makers use only lime in the boiling process, whereas others use pot and pearl ashes to a considerable extent; but we believe that a ley composed of soda and a portion of quicklime is most commonly employed.

The rags, after being thoroughly cooled, to which a gentle flow of cold spring-water let into the boiler materially contributes, are laid aside in large wooden chests for use, or at once conveyed in boxes on wheels into the engine-house, there to be reduced to pulp. As this is one of the most important processes, and requires the whole power of the mill, we shall explain it, with reference to Plate CCCCIII. This plate represents a plan and elevation of a paper-mill for four engines, EE. W is the water-wheel, on which there are segments, S, of cast iron, which work into a main pinion P. This pinion is fixed on the same lying shaft on which the spur or fly-wheels F are also hung. The motion is thus brought up to the proper speed, it being necessary that the pinions *p*, *p*, *p*, of the engines, and the engine-cylinders *c*, *c*, should perform about 150 revolutions per minute.

The engines, fig. 1, which are to be understood as large troughs of an elliptical form, with a division *d* running nearly the length that intervenes between the foci of these imaginary ellipses, consist of two sorts, according to the purposes to which they are applied, viz. washing and beating engines; the former being designed for washing and rubbing out the rags, and the latter for shortening or beating down the fibres, after the washing and bleaching processes have been performed.

These engines are generally made of strong wood, and lined inside with lead or copper; but for some years past they have been very successfully cast in iron, all in one piece, although, from their awkward shape, it may be easily conceived to be rather a difficult matter to insure a good casting of such a mass. They measure about ten feet in length, four and a half feet in width, and about two and a half feet in depth, being dimensions sufficient to contain about 112 or 120 pounds of rags. From the rapid motion and weight of the machinery, and great friction necessary to triturate the stuff, it is evident that the solid fixing of the engines is a matter of extreme importance. It is usual, therefore, to build, from a solid foundation, a substantial mass of ashler work (fig. 2, A A), of the size of each engine, for it to rest upon.

The cylinders in the engines, technically called the rolls, and by the revolution of which the rags are ground into pulp, are formed in general of solid wood. Elm is most generally used for this purpose. They are commonly about two feet in diameter, and two feet in length. Round the circumference are firmly fixed bars of steel parallel to the axis or spindle, in bunches of two together in the washing engine, and three in the beating engine, generally about eighteen or nineteen several bunches, and making therefore in all about thirty-eight bars in the washing engine cylinder, and fifty-four or fifty-seven in that of the beating engine. These steel bars are sunk and wedged into the circumference of the cylinder, parallel to the axis, and are, moreover, firmly fastened by means of hoops, which are fitted into a groove in the ends of the cylinder, and, passing through the bars at a place cut out in them for that purpose, secure them firmly in their place.

Under the cylinder is what is called a plate, see fig. 2, that is, a number of steel bars, which lie fixed in a place

---

[1] A sketch of a chest of this description will be found under the article Bleaching, vol. iv. p. 683.

provided in the trough *b* for them. They are accurately fitted, so as to form a segment of the same circle as the cylinder itself. The number of bars varies according to the kind of work performed at the mill; but in white-paper mills, in the washing engines, the plate has generally from twelve to eighteen bars, and in the beaters from twenty to twenty-four. The breadth of the plate is almost universally the same everywhere, namely, from five and a half to six inches. A plate six inches broad is found to require quite as much power, from the increased friction, as can in general be spared.

The thickness of the bars in the washing-engine plate is generally from about three eighths to half an inch; and in the beating engine from about three sixteenths to one fourth of an inch. In the latter they are made up with wooden or copper dividers, so as to afford the necessary thickness, in all of five and a half or six inches. The thickness of the cylinder and plate-bars ought to be about the same proportion to each other: they are bevelled or tapered off about an inch or an inch and a half from the edge, like a wedge; and those in the washing engine being intended for opening and rubbing out the cloth and duly washing it, it is the opinion of the writer of this article that they ought not to be under the thickness of one eighth of an inch, and in the beaters under that of a shilling at the edge after being ground, otherwise, by the too rapid conversion into pulp, the strength of the fibre would be materially injured.

The rags having now been boiled, and brought into the engine-house, the workman, or engineer as he is called, fills the engine or trough about half full of water, till the bars of the cylinder, which project fully an inch from the wood, get hold of the water, and begin to turn it round. He then begins to put the rags into the engine, and spreads them with his hand. By Plate CCCCIII. fig. 2, it will be seen that the spindle *s*, which goes through the cylinder, is supported in its bearing upon an iron lever, called a lighter, *l*. A screw *h* is attached to it, and by moving that screw, the cylinder can be raised about three inches above, or depressed so as to come into contact with the bars of the plate.

Behind the cylinder it will be found that there is a rise (fig. 3, *r*) in the trough, which, on the side next the cylinder, forms a segment of a circle similar to that of the cylinder, and within an inch or two from it, and then descends by a rapid declivity from the point *t* to the natural bottom. This rise is called by the workmen the *backfall*, from the rags falling down upon it. The cylinder is always, when the mill is at work, enclosed in a wooden cover, fig. 4. The cover of the washing engine has four slits or grooves cut down through the top of it, two on each side of the cylinder. The two slits *w* next the cylinder are made for a board of wood *w*, which can be put in or removed at pleasure, being guided by grooves in the inside of the cover. The other two slits *c* receive two frames of very fine copper-wire cloth *c*, having about 4900 holes in every square inch. These wire-cloth frames are generally fixed, being only taken out when any repairs are requisite.

The rags being now filled into the engine, the cylinder, by means of elevating the screw (fig. 2) *h*, is raised as high as it will go, as there is thereby room for a greater quantity of water being carried round with the dirty rags, and driven by it, in its rapid revolutions, against the wire-cloths. In the bottom of the trough, see fig. 1, there is a false bottom *f*, which is punctured through by a number of small holes, and which communicates with a cock O. This cock, when kept fully open for the first twenty or thirty minutes, has the effect, in consequence of the pressure of water and suction, of carrying off a great deal of dirty water, as well as sand and loose particles from the rags, which have escaped former cleaning operations.

When the engine has been once filled with rags and water, of which there must be a large supply constantly flowing, the cylinder, by its projecting bars, working like the paddles of a steam-boat, draws them in. It then throws them up to the top of the back-fall formerly alluded to, dashing a portion against the two wire-cloths, through which the dirty water passes, and the rags or stuff remain. A great portion of course descend the inclination at the back-fall, and by this means produce a regular progressive motion of the stuff, which comes again and again under the action of the cylinder bars and plate. The cylinder is gradually depressed as the washing goes on, till it comes as nearly as possible in contact with the plate at its lowest point. The plates are not placed directly in line with the bars of the cylinder, but lie at an angle of about five degrees. This prevents the one from being locked against the other, should the cylinder, from any cause, be too much depressed; and it is moreover necessary that they should be in that position, to promote the reducing of the rags to pulp, on somewhat of the same principle with the cutting process performed by a pair of scissars, the one blade forming an angle with the other.

To make good paper, a great deal depends upon the state of the engines, bars, and plates. If these be not in proper working order, and well fitted together, and adapted for the description of material worked, it is impossible that any subsequent care can remedy the mischief done in the engine-house. It is much to be regretted that the great demand which has prevailed for paper for many years past has induced manufacturers generally to sacrifice quality to quantity, by hurrying the process, which impairs the strength of the fibre, and injures the texture of the paper.

Mr John Murray of Hull has paid considerable attention to the state of modern paper, and has contrasted its condition with that which was made thirty or forty years since, greatly to the disadvantage of the former. Mr Murray, who has pointed out the value of the *Phormium tenax*, or New Zealand flax, as a substitute for hemp in making cordage, and who has also printed and published a pamphlet (in 1836) upon paper made of its leaves, which, though coarse, is remarkably strong, thus writes, in a postscript appended to that work:—"The unquenchable rage for bleaching that now prevails is carried to an extent altogether irrational, and which our calmer judgment would condemn if suffered to interpose. Paper, when bleached, if the chloride be not removed, or permanently neutralized, produces effects of the most disastrous kind." Mr Murray then refers to a number of recent publications, which, he alleges, are rapidly crumbling into dust; and seems to attribute the whole evil to excessive bleaching. Whilst we admit the ruinous effect on the fibre, of bleaching to excess, and whilst we also admit that there is much truth and justice in Mr Murray's remarks, we do not share, to the same extent, in the alarm which he experiences in contemplating the speedy ruin of the books and manuscripts of the present day; and we are rather disposed to attribute the evil complained of, not by any means so much to excess of bleaching, as to the hasty preparation of the stuff in the engines.

In any former treatises on paper-making which we have seen, we observe that the trituration of the rags is described as an operation of cutting. If the bars and plates of the washing engines are kept so sharp as to cut the rags, nothing can be conceived more injurious. Every paper-maker knows that the stuff is rendered mellow and soft, by being rubbed out by blunt bars and plates. The longer the time occupied by this operation, the more water will the stuff incorporated with it hold when it is worked into paper, and the less easily will the water drain off from it, which is always a sign of strong paper. Stuff, on the other hand, which has been quickly prepared by sharp tackle, never has the water properly beaten up with it; but the fibres, having been *cut* down, as it were, are held in suspension in the water merely, and the paper made from such stuff is always weak, flimsy, and perishable.

An abundant supply of fine water is very essential to produce paper of fine quality. When the rags are first begun to be washed, the engine consumes about a hogshead per minute for the first half hour; but this quantity is soon diminished by the rags being opened up into pulp, and thereby taking up more room for themselves in the engine, till, towards the conclusion of the washing process, the water which passes through the wire-cloths does not amount probably to one-twentieth part of that quantity.

In reducing the rags to half stuff, about three or four hours have been hitherto considered as necessary for fine papers; but, from the desire to produce a large quantity, it is the practice of most machine-mills now to do this in half the time, to the very great injury of the fabric. The power required to keep each of the cylinders moving the stuff, when pretty near to the plate, is equal to about five horses.

The rags having undergone the process of being washed and *broken in*, that is, rubbed into half-prepared pulp, the engineer shuts off the supply of washing water, and then, by means of an iron hook two feet and a half long, which he inserts into the cavity of a conical brass valve, fitted into a pipe at the bottom of the trough or engine, raises that valve, and the half stuff then flows through a pipe of about six inches diameter, into the bleaching-house, situated in the under story, where it is received into a draining-chest of pretty large size, and suffered to part with the water, which flows through a number of very small holes bored in the wood. As soon as the stuff is emptied, the washing-engine is again filled with rags, as before.

The bleaching process is carried on in some mills by the rags being subjected in close chambers to the action of chlorine, which is produced in leaden retorts, from sulphuric acid, sea-salt, and the black oxide of manganese, and for an account of preparing which, we refer to the article BLEACHING. In a great many mills, however, where this mode was long carried on, it has been entirely abandoned, and the practice of steeping the rags in a solution of chloride of lime has been very generally substituted, particularly in Scotland. The advantage, in the latter process, consists in the stuff not being so much injured in the fabric as if exposed to chlorine itself; and although the whitening effect may not be produced so speedily or completely as if done by the action of the gas, yet, by giving the steeping process plenty of time, that is nearly compensated for, and there is much less waste in the latter than in the former process.

The bleaching house for steeping consists of a long apartment, according to the number of sheets necessary for the extent of the works, and about sixteen feet wide. A passage of three or four feet wide goes down the middle, and on each side are arranged stone chests about three feet deep, and containing about fifty-seven cubic feet. In each there is a false bottom, which has been made of many different materials, none of which is so good as could be wished, to resist the action of the chloride, and which, therefore, require frequent renovation, viz. lead, copper, wood, stone, slate, &c. The false bottom is pierced through with a number of holes, as small as can be made; and under the false bottom there is a small pipe, into which a valve is fitted, and attached by a wire reaching up to the top of each chest, by pulling which, the liquid is allowed to escape at pleasure into a large tank, extending under the whole of the chests. In this tank is sunk a pipe, with a pump, for the sake of raising the liquor. Although this solution be now very weak, yet it is much better than pure water, and therefore it is so far eligible to make use of it.

The half stuff having come down from the washing engine into the draining chest, which is situated about three feet higher than the level of the stone bleaching chests, and being now freed by drainage of a great part of the water with which it descended from the engine, a part of one of the sides of the draining chest, being a kind of door on hinges, is opened, and the stuff is promptly raked into an iron square box lined with wood or metal, which moves on a railroad fixed along the passage above referred to, and is carried to each of the chests in succession, as they are ready to receive the stuff. About one hundredweight of rags is laid in each chest, and receives upon an average from six to eight pounds of Tennant's strong saturated chloride of lime, according to the quality of the rags, in solution with about twelve gallons of water; and the chest is then nearly filled up with the weak liquor pumped from the tank. Great care is necessary to keep the stuff frequently stirred, otherwise the whitening throughout would not go on regularly. It is always found, that from the effect of the air and light, the upper stratum of the stuff in the chests becomes white, whilst what is under is for some time but little affected.

The stuff is allowed to remain in the steep for twenty-four hours before the liquor is allowed to drain off, and of course there must be as many chests as there are hundredweights of stuff prepared in the twenty-four hours; but it is found not to have reached its maximum of whiteness even in twenty-four hours, for the stuff which has been set to steep on Saturday, is always found on the Monday mornings to be of a somewhat purer white than on any other morning.

After the time for steeping has expired, the stuff is again lifted into the iron box formerly mentioned, which, being full of stuff, is moved on the railway till it is placed on a moving sole of a Bramah hydraulic press, which is situated in a convenient part of the passage; and the water being injected by pumps moved by the machinery of the mill into the piston of about ten inches diameter, causes by its great pressure the iron sole, with the wet bleached stuff upon it, to rise against a wooden *ram*, as it is called, of the exact size of the box containing the stuff. What remains of the chloride in solution, as the ram enters into the box, is thus gradually pressed out, and flows into the tank formerly mentioned as situated under the chests. The ram enters into the box about one half of its whole depth, and it will be seen by the annexed table what space is occupied by a hundredweight of the material in its raw and manufactured state at different stages of the process.

One hundredweight of linen rags cut, but not pressed, occupies a space of about..	5½ cubic feet.
When in the washing engine in process of washing..	46 ...
When drained of all the water that will flow from it..	25½ ...
When pressed by the ram........................	7½ ...

The object of pressing out the liquid weak chloride of lime is to lighten the labour of raising the stuff to the higher story of the engine-house again, and also to render the process of washing it out the more easy; for it is most essential that none of the bleaching matter should be left in it.

This washing is performed in precisely the same way as that of the rags, and goes on for about an hour, after which, in the same engine, the pure water being shut off, and the boards in the cover of the engine being put into their places, the pulp is reduced considerably in length of fibre in the same engine with *blunt* tackle, which tends to soften the stuff, and make it mellow. The engine which is specially set apart to wash out the remains of the chlorine, and to soften the stuff, is sometimes called the intermediate engine; the stuff being now half way between rags and paper, and called *half stuff*.

The stuff is then let down to the beating engine by lifting a valve in the pipe, and it is then beaten down by tackle considerably sharper than that in the washing engines. The stuff is here, as it were, combed out into fibres of perhaps one eighth of an inch in length, and this operation for fine paper ought to take from four to five hours; and, from the friction between the cylinder bars and those of the plate, the stuff ought to become moderately warm. It is now in a condition to be made into paper; and, by a valve being lifted, it flows out of the beating engine by a pipe which conducts it to a large stone or wooden reservoir called a chest in the vat-house or machine-house.

Making paper by the hand.

The apparatus for the formation of the paper in single sheets at a time by the hand consists of,

1. A chest for receiving the prepared stuff, and which, if there be enough of fall in the situation, it is extremely desirable to have situated about three feet higher than the vat, in order that the stuff may flow from the chest to the vat gradually as it is worked into paper, otherwise it must be lifted by a lad at intervals by means of a copper pan.

2. The vat, which is a stone vessel about six feet square, and about four deep. It is agitated by a *hog* or little wheel about twelve inches in diameter, which revolves through the whole length of it to keep the stuff constantly stirred; for the fibrous particles, being heavier than water, would otherwise sink.

3. The moulds or frames, of which a pair is required, so that when the vatman is dipping the one into the stuff, the coucher may be placing the sheet on a layer of felts, of which from four to eight quires, according to the size of the paper, form a *post*, that is, the whole quantity which is brought under the press at one time. The vatman stands at one side of the vat, and the coucher at the far corner of the side, on the vatman's left hand, and facing him; and between them is a narrow ledge of wood, on which the mould is sent from the vatman to the coucher. The vatman always holds in his hand a frame of wood called a *deckle*, which is about an inch broad, and is made to fit exactly all round the edge of the mould, for the purpose of forming a clean and not a ragged edge to the sheet; it is this which is called the water-edge, and which is so easily distinguishable from any other species of edge than can be otherwise produced as to have been generally adopted in paper used for bank-notes. This description of paper is in consequence generally made on moulds of the size of the note, that it may possess the water edge, for the purpose of rendering forgery more difficult.

The moulds are made of brass wires or wire-cloth fixed upon a wooden frame, which is generally made of mahogany. A number of wooden ribs are fixed across the frame, placed at intervals of about one inch from each other, for the wires or wire-cloth to rest on. When *wires* only are used, these are *laid* longitudinally along the frame and across the wooden ribs, and interlaced with a wire somewhat thicker than the wires running lengthways, which is placed on the top of each rib. Paper made on such moulds is called *laid*, in contradistinction to what is made off the *woven* wire-cloth, and which is therefore called *wove* paper.

When the vatman dips the mould into the vat with the deckle upon it, he takes up a quantity of the pulp, which has been previously mixed with a great deal of water, and well agitated by the *hog:* he then throws off a great portion of the stuff and water over the edge of the mould farthest from him, and bringing the mould to a horizontal position, shakes it to and from him, which connects the fibres together so as to form one uniform fabric, and shakes out the water. To attain this method perfectly requires a long apprenticeship, simple as it may seem. As soon as the pulp is no longer in a liquid state on the mould, the workman raises the deckle with his fore-fingers and thumbs from off the mould, and with his remaining fingers shoves the mould along the ledge before referred to, to the coucher, who is ready to receive it, and who places it in an inclined position upon a small wooden curved stay, on which it reposes for a few seconds, that the water may be further drained from the newly-formed sheet. The coucher is in the mean time pitching a felt or piece of blanketing upon a wooden plank of the proper size, and then takes the mould and presses the face of it upon the felt, which receives and takes off the sheet of paper from the mould, still in a very wet state. The mould, being now freed of the sheet formed upon it, is pushed back along a wooden bridge, as it is called, which is joined to the ledge, and is placed at right angles to it. The bridge crosses the vat in front of the vatman, and the mould lies on it ready to be used by him, whilst the other mould is employed by the coucher. The process is continued till all the felts, being placed above each other with a sheet between each, are employed, which takes about half an hour. A heavy plank is then placed on the top of the *post*, as this quantity is called, and the whole is drawn in on a railroad, or rollers, under a press which is contiguous, and where the water is squeezed out, either by means of a screw, or by a Bramah hydraulic press. The paper, when it comes out of this press, is so coherent as to admit of being handled, and the sheets are accordingly laid together in a pack by themselves, the felts being placed on a wooden deal between the person who takes off the sheets from the felts, called the layman, and the coucher, who immediately, with the aid of the vatman, begins a new post. The water-mark is produced by wires in the shape of the letter or design being raised upon the surface of the mould.

After a number of packs have been made, they are put into another press, where they are made to *sweat* by pressure; that is, just to part with a small quantity of water, which comes from them in single drops. If the pressing be carried on too quickly or too long, the paper would be damaged by the sheets adhering to each other, and *peeling* or tearing when attempted afterwards to be separated.

The paper is then parted sheet by sheet, so as to be enabled to undergo another pressure before it goes to the loft to be dried. In fine writing paper it is the practice to part the paper twice over, pressing between each parting. This is to make the sheets lose the marks of the felts, and to get the paper as dry as possible before it goes to the loft.

The lofts consist of a number of spaces filled with *tribbles*, that is, hair-ropes fixed into spars of wood, the ends of which are made to slide up and down the upright posts of wood, one of which is fixed at the corner of each space. The paper is hung up in *spurs*, as they are called, of five or six sheets thick, upon the ropes, by the help of a wooden cross, shaped somewhat like the letter T. The workman holds this cross at the lower part of it, and the top of the cross must be as long as the width of the sheet. The dryworker then, with his left fore-finger and thumb, pinches the corner of the hard-pressed *pack*, which has undergone one, two, or, if fine writing paper, three, hard-pressings since it left the felts. He then partially raises by that corner the spur of five or six sheets, and with the cross gently catches the paper, which he slips over the hair-line, and leaves it there suspended. The pack is placed on a table which moves on small wheels, and against which the workman stands, and which he can push or draw with ease to any part of the loft that he pleases. When the tribble lines are all full, he pushes up the sides or spars upwards along the upright posts, which are bored all the way up for small pins of wood that support the tribbles; about eight or nine tribbles fill a *room*, as it is called, that is, each space. The sides of the lofts are boarded with spars of wood, placed vertically, about four inches wide and four separate. Inside of these are shutters made exactly similar, but fixed on wheels which move in a groove, so as to shut in the loft entirely or partially, or leave it open, according to the state of the weather. Many lofts have, in addition, woollen curtains within the shutters, which, with the addition of the heat derived from steam carried round the loft in pipes, are most serviceable for drying when the state of the weather renders it impracticable to dry by the air.

When the weather is favourable, the paper, before being sized, may be dried in twenty-four hours. After being sized, it ought not to be dried in less than three or four days, as by too rapid drying the size has a great tendency to fly from the paper; and therefore, when hung up after undergoing this process, the shutters are, in general, immediately closed upon it, so as to make the drying as gradual as possible.

Messrs Cowan's drying lofts at Valleyfield Mills, near Edinburgh, are perhaps as extensive as any in the kingdom. The paper is brought up to the loft by a crane on a scale, which is then in the loft placed on a carriage upon wheels, that moves on a railway along the centre of the lofts, forming a continuous line of about 360 feet in length. There are about 60 rooms or spaces, with nine tribbles in each, making about 500 tribbles in all, which, when filled, hold about 1200 reams of post paper.

The paper up to this point is quite bibulous, and therefore unfit to bear the ink. It is therefore transferred, when dry, to the sizing-house. The size is made from the refuse of tan-yards, called *scrolls*, consisting of the parings of skins, pates, ears, &c.; which materials range in price, according to quality, from L.20 to L.40 per ton when thoroughly dried. The scrolls, as these pieces are called, are boiled for about ten hours, and the gelatine gradually and carefully strained off through straw, branches of trees, charcoal, &c., and lastly, through fine flannel bags. An addition of alum to the amount of about one fourth of the weight of the scrolls is then made. The size is run into chests or casks for use, where it soon congeals. When run off it is much too strong to size any description of paper with. When the sizing operation is to proceed, therefore, it is mixed up and diluted with water, in a small boiler, and heated with steam. From the boiler it is made to flow in a spout into a tub of about five feet square, which is also heated with steam introduced under a false bottom, it being very essential to use it always very hot. An additional quantity of alum is also made use of, which is placed in the spout, and is gradually dissolved as the size flows down in contact with it. The workman stands close to the tub, and dips the paper in handfuls, containing about six quires on an average, with a wrapper at top and bottom, which he soaks thoroughly, turning it backwards and forwards, so that every portion becomes completely penetrated with the size. It is also allowed to remain some minutes soaking in the tub, being held by wooden pincers suspended by a balance-weight. He then carefully lifts them out one by one, and places them in a press, adding to the heap till the press is full. The surplus size flows, and is then by a moderate pressure squeezed out of the paper, the edges of which are next rinsed by hot water, before the pressure is taken off, to prevent them from adhering together; and with the same view the heaps of paper, when taken out of the press, are enveloped with woollen cloths, so as to exclude the cold air.

Moreover, to prevent the paper from sticking when it is strongly sized, it is separated or parted sheet by sheet, after which it is pressed moderately, so as to make the *spurs* slightly adhere together. It is better to keep the sized paper forty-eight hours before hanging it up to dry, and then the more gradual the drying the better.

Another mode of sizing, which tends to save both labour and wrappers, is by means of a machine or wooden table about two feet from the floor, above which are placed two spars of wood parallel to each other, supported from the table. The spurs of paper are placed vertically on the table, that is, their long edge resting on the table and across it; and between each spur a thin slip of wood is introduced, which is attached to the spars of wood by means of hooks and eyes. The slips of wood are then pressed somewhat tightly together, so that the whole mass is easily raised, by a pulley fixed overhead, to a small carriage, by which the paper, when raised from the table, and thus suspended in the air, can be wheeled right over the tub, into which it is let down to receive the size. This tub is divided into two compartments by a wooden sole affixed to a screw, which lies horizontally, and is worked by some wheels, so as to press the paper. The paper, when let down into the other portion of the tub, has the frame and slips hooked away from it as soon as it is gently pressed by the screw, so as to keep it from falling down. The hot size is then allowed to flow in amongst the paper, on which, when thoroughly soaked with size, the screw is made to work, and to press it. A board which has been pressed down against the paper is now fastened to a board of similar construction by means of strong iron clamps, and the screw is worked back again, leaving the paper still under pressure. A strong false bottom of wood, on which the paper rests, is now raised by means of a rack and pinion, and with it the paper and the heavy planks confining it, above the liquid size; and whenever the pressure is removed, it is at once set aside as sized. The size left in the tub is then pumped back to the boiler to be again heated.

There cannot be a stronger evidence of the necessity for the stuff being well prepared, in order to obtain a sound paper, than the process of sizing. If the stuff has been slowly prepared by trituration, so as to hold a good deal of water, it will also hold and keep the size in a manner corresponding thereto; whereas a quickly prepared stuff, which has been cut rather than rubbed out, however strong the size that may be employed, can scarcely be got to keep it. It is also very injurious should any of the chlorine or chloride of lime be left in the paper unwashed out, as the glutinous matter is thereby decomposed, and rendered of no avail.

After the paper has again been thoroughly dried, it is taken to the *salle* or finishing-house, where it is pressed very often in order to take out the marks of the lines, and to improve the surface generally.[1] The hot-pressing is carried on by means of smooth paper boards which have been glazed by passing through metal rollers. The paper is placed alternately between these, and heat is communicated by hot iron plates being laid upon these at intervals of about six quires. These plates are heated in an iron box, into which a supply of steam is sent, and where they do not generally require to be more than five or ten minutes. These plates, by means of pressure, communicate a good deal of heat throughout the paper, after it has been all brought under the action of the hydraulic press.

---

[1] A very laborious operation, and one injurious to the paper, used to be performed in the salle; that of picking out the knots and lumps in the paper by means of small knives. The paper could not fail to be injured by this system of scraping, and the ink was always apt to sink where it had been scraped; but this operation is now rendered almost unnecessary by the invention of the strainer, through which the pulp is strained before it passes into the vat.

In consequence, however, of the general use of steel pens, and perhaps to some extent of the fashion of the day, it is necessary to finish fine letter-papers now with a much higher gloss, and various methods have been adopted for this purpose. One of these methods consists in using, instead of the hot-pressing smooth glazed boards, copper plates made very smooth, on which the sheets of paper are laid, a copper plate and a sheet of paper alternately. These, when filled with about one quire of paper, are passed between a pair of iron rollers, where the pressure is equal to twenty or thirty tons, and which are driven by the machinery of the mill. By moving a clutch, a small wheel is thrown in and out of gear at pleasure, so that the workman can instantaneously reverse the motion of these rollers, and they can be made either to take the copper plates away, or to return them again towards him after they have passed through, so as to sustain the pressure twice over. Another workman attends on the other side of the rollers to return the copper plates. It requires three women to be attending to fill and empty each set of copper plates, one filling in the rough, another taking out the smooth paper, and the third lifting off the copper plates in succession, and placing them on the sheets of paper as these are laid down. When the paper has had three or four pressures, it is pretty smooth, and is then denominated *rolled* or *hot-pressed;* but if it be passed more frequently through the rollers, it acquires a higher surface, and is then called *glazed.* Each set of three women can in this manner fill in about twenty reams of paper in one day. The work is laborious, from the quickness with which it is done; and, from the sharp edges and corners of the copper plates, and of the paper itself, the women are very liable to have their fingers cut, so that this department of work is not very popular, and in some manufactories it has acquired the name of the *tread-mill.*

Another mode of giving a higher surface to paper is by passing it through a calender, or cylinders which have been made of cast iron, copper, or brass, or one of them, like the ordinary calenders, consisting of a paper bowl. But these, although they be accurately fitted and polished, are all more or less liable to receive marks or indentations from any minute hard substances, or from folds or creases which may be in the paper, and which they give out again, and thus mark the paper.

The paper is now, after being rolled or glazed, told out into quires or half quires, folded, and made up into reams, and is subjected to pressure under hydraulic presses in every stage. It is then tied up in a wrapper, with a label on it, for the protection of the duty, and, the label being filled up by the trader and officer respectively, the paper is weighed by the latter, and stamped, so as to denote the amount being charged against the maker. The trader is allowed to keep his uncharged paper in bond, so that he is so far more favourably situated than those who follow many exciseable trades, where the duty is levied on the raw material, or on the article in some process of manufacture. The regulations deemed necessary to protect the revenue are abundantly complicated and contradictory; but it must be allowed that, within the last few years, a disposition seems to have been manifested, both by the Board of Excise and their officers, to afford every facility, and cause as little annoyance as possible to the manufacturer; whilst the officers are now, generally speaking, a much more respectable and efficient class of men, than when their ranks used to be recruited from the decayed lacqueys and dissipated butlers of the gentry; and undeniably the appointment of Sir Henry Parnell's Commission of Excise Inquiry in 1833 has tended much to promote the comfort and freedom of the trader, and, at the same time, to afford additional security to the interests of the revenue.

Machine paper-making.

Hitherto we have considered this manufacture as carried on by the hand. The papers made in that way are, for the most part, fine writing papers, into which it is necessary to introduce the water-mark, showing the maker's name on the mould. As the machine cannot have a water-mark nor make any paper except upon a *wove* wire-cloth, all water-marked and laid paper is necessarily made by hand.

The stuff having come from the engine-house in pipes, and being contained in large circular chests or reservoirs ready for use, is in them kept constantly stirred by wooden agitators, so that it may not sink to the bottom, or flow out on the machine in thick and thin portions.

Fourdrinier's machine.

The machine which is now used so universally all over the kingdom is the invention of a Mr Louis Robert, and was brought to this country by M. Didot of Paris, who came over to England about thirty or forty years ago, and, with the assistance of the MM. Fourdrinier, and Mr Donkin the engineer, succeeded in perfecting the invention, and in acquiring a patent right, which was afterwards renewed for a longer period by parliament, in consequence of the patentee's not having derived sufficient compensation.

The stuff flows out of the chests CC, Plate CCCCIV. by a pipe *p*, on which there is a cock *b*, which the machine-man opens more or less wide, according to the thickness of the paper to be made. It falls into the spout *s*, where it meets a large supply of water, which has been in great part passed through the web of pulp before, as will be afterwards explained. It then falls into the vat at the opening of the spout, and is there agitated by the little hog, as it is called.

A very important improvement has, however, been introduced at this stage, which, though not part of MM. Fourdrinier's machine, is now universally applied to it. We allude to the straining of the stuff, and thereby keeping out of the paper all the knots and hard substances which it was formerly necessary to scrape out in the salle, to the great injury of the surface of the paper. The strainer is an American invention, and has been introduced into England for about nine years; and a patent is now enjoyed for it by the Messrs Ibotson of Poyle Mill, Buckinghamshire.

The strainer is generally used before the stuff flows into the vat. It consists of a brass rectangular trough of about five or six feet in length by two feet in width, with sides about four inches deep. The bottom consists of a number of heavy bars of brass, the surface of which is perfectly planed and polished. They are about one inch in breadth, and can be taken out at pleasure. When the strainer is at work, these bars, which rest on a projecting ledge, and which are very firmly fixed in by wedges, &c. are placed so as almost to be in contact along the whole of their well-fitted edges; and the spaces between them at the sides are occupied by thin wedges, of such a size as to correspond to the length of the fibres. The strainer is driven by means of a light iron or brass shaft which passes above it, and has two small notched wheels, one placed above each end, and working into the frame of the strainer. When the shaft revolves, therefore, it will be seen that at every notch the strainer is raised, and then quickly descends by its own weight, so as to produce a continual jerking motion, making about a hundred and thirty strokes per minute. The stuff is now flowing in, and the bars are placed so close to each other that the fibres must necessarily pass longitudinally. The knots, &c. are therefore kept back, and as they accumulate in the strainer, the workman, with a wooden rake, draws them towards himself, then shuts off the flow of the stuff in that direction by means of a kind of sluice, composed of a piece of wood, which is covered with felt, and which is pressed in across the strainer. The end of the strainer next the workman is therefore left dry, and with a thin piece of copper or other metal he scoops up the knots, &c. takes out the sluice, and repeats the operation when it is required.

After the stuff has been thus strained and mixed in the vat by the agitator working in it, it is allowed to flow out by a number of holes in the side of the vat. These holes are of an oval figure, about four inches long by two in width; and against each of them is accurately fitted a brass plate, attached to a rod. This rod is worked by a screw in the workman's hand, who can thereby again regulate the flow of the stuff into a little cavity or box at *c*. From this point a piece of leather or apron extends to the point *t*, from whence the stuff flows on an endless fine wire-cloth, on which the web is formed. This wire-cloth, which must be perfectly level, moves upon a number of small copper rollers, about an inch and a half diameter and an inch and a half separate. These rollers rest upon a frame, which is left so far free as to be moved laterally by a rod which is attached to a little crank *e*; and thus is produced a vibration, more or less quick, according to the nature of the stuff, which causes the water to flow through the wire-cloth, and connects the fibres of the pulp together. A large shallow wooden vessel is placed below the wire-cloth, called the save-all, which receives the water and the flour of the pulp in large quantity. The water then passes through a spout on the side of the machine, and flows into a box, from whence it is lifted up by the scoops *f*, and then meets the supply of stuff from the chest, and flows into the vat.

The edges of the paper are formed by pliable deckles, which were formerly made of leather, then of woollen cloth. Belts or deckles, however, composed of alternate layers of linen and caoutchouc, firmly cemented together, are now most generally employed. These belts are half an inch thick and about sixteen feet long, and are drawn by the pulley upon the shaft *g*. It will be seen that they move under a solid plate of iron or brass, which is moderately pressed down upon them, but not so much so as to impede their free motion along with the wire-cloth, whilst they fit sufficiently tight to it to prevent any of the stuff from flowing away laterally before the paper is set.

By the time these caoutchouc deckles leave the wire-cloth at the point *p* the stuff is no longer fluid, though a good deal of water still flows from it. The wire-cloth then passes on with the pulp upon it through the cylinders *ii*, of which the under one is of metal, covered with a jacket, as it is called, of felting or flannel; and the upper one is generally of wood, but hollow, and covered with mahogany about an inch and a half thick; that wood being less apt to shrink or get out of shape than any other; and this roller also has a jacket. A slight pressure is given by these, which are called the wet-press cylinders; and after this stage the paper pulp is led on upon an endless felt, which must proceed exactly at the same speed as the wire-cloth, as, by any irregularity in their motion, the pulp would break. The wire-cloth returns back round the under wet-press cylinders, to receive a new supply of pulp, and is supported by a series of copper tube rollers, which revolve by the friction of it. The wire-cloth is generally about twenty-five feet in length by five feet in width, and has about sixty holes in the lineal, or 3600 in the square inch.

The web of paper, still in a very wet state, is now carried away by an endless felt, between cast-iron cylinders *kk*, where it sustains a severe pressure, and where a great deal of water is squeezed out, after which the paper may be handled. It then passes through a second pair of press cylinders, that the mark of the felt which was impressed on the under surface by the first pressure may be removed; and for this purpose the under surface is now placed next the metal cylinder. The web then passes over the surface of a number of cylinders, heated with steam, and arranged as to number and relative position according to the ideas of the manufacturer or millwright. When the web has passed over about thirty lineal feet of surface heated in this manner, it is dry, and is wound upon a reel *l*.

When this reel has been filled, or has performed about a hundred and thirty revolutions, a spring, which holds in the ends of the reel, is taken out. The reel which is attached to the arms *m*, which move on the axis *n*, is moved quickly round, and changes places with the other reel, when the paper is torn through, and the end of the web is then attached to the reel in gear, which is filled, whilst the paper is being cut off the reel which is at liberty.

The paper machine moves at the rate of from twenty-five to forty feet per minute. The whole process, therefore, in its transition from liquid pulp at the one end, to dry paper at the other, occupies scarcely two minutes. This, in the ordinary state of the weather, could not formerly be done in less than seven or eight days. Supposing, therefore, that the machine makes ten yards lineal of a web per minute, or 600 in the hour; this is equal to a mile in three hours, or four miles per diem of twelve hours. The paper is generally made about fifty-four inches wide. Reckoning that there are 300 machines in Great Britain, and that they work twelve hours each day on an average (many go both day and night), the length of web would altogether be equal to 1200 miles, and the area of what was made would be about 3,000,000 yards daily.

Printing paper, which is now entirely made by the machine, is in general sized in the pulp. White soap, starch, glue, and dissolved rosin, are principally used for this purpose, with the addition of a few pounds of alum. Such of these as are used are put through a sieve into the beating engine. The web, before being dried off, is also in some mills passed through hot size, the surplus of which is pressed out between two cylinders. This tends to strengthen the paper materially; but it is not easy for paper to keep the size if it be dried off hastily on the cylinders; and this is difficult, if not impossible, in the finer descriptions of paper, where the material is not so strong as that for more common kinds, and not so favourable for being thoroughly sized.

The fine bluish tinge which so many writing papers possess is derived from a mineral but very expensive blue, namely, the oxide of cobalt, generally called smalts. This article used entirely to be imported from Saxony, Denmark, and Sweden; but the great improvements which have been effected by British manufacturers of late years have rendered it unnecessary to seek a supply abroad. In writing paper of fine quality it is usual to add four or five pounds of smalts to the hundredweight of rags.[1]

Cutting machines.

Several machines have of late years been invented for cutting paper as it is made by the machine. Amongst others, one by MM. Fourdrinier of Staffordshire has been very generally introduced and approved of. As it is capable, however, of cutting five or six thicknesses of paper at once, it is not in general attached to the machine, but in some contiguous convenient place. The paper is reeled on small rolls of about six inches diameter, and these are placed with the spindles lying in grooves in a curved frame, whence they are taken and passed round a drum, and then through some small rollers. After the web is divided longitudinally by circular knives, which are set opposite each other upon shafts on each side of the paper, the progress of it is stopped for an instant by a very ingenious contrivance, when a knife descends, beginning at one side of the web, which is held fast by a heavy weight laid across it, and cuts it across. The web then goes on till it has passed as much paper through as is the requisite size of the sheet, when the knife again descends. The sheets thus cut are carried on by a small felt moved in connection with the rest of the machinery.

---

[1] This blue is now greatly cheaper than it was during the war, and even after its termination, having fallen from 2s. 6d. to 1s. 3d. per pound, which last is the present price for *FFFE* smalts.

The paper-machine is peculiarly suited for making thin papers, which are not easily made by hand without great damage in the couching department, from the difficulty of getting off the sheet whole upon the felt; namely, the thin paper for copying letters, tissue-papers used for putting before prints, &c. A large quantity of remarkably thin paper, also, made from old ropes of a better description than usual, and called pottery tissue, is made by MM. Fourdrinier and others, for printing the colours on the china, &c. which could never have been made by hand. The machine has also been of immense service in producing paper of large sizes of sheets for newspapers, which could not have been worked by hand. It would have been very serious and laborious work for a man to make paper even large enough for a single sheet of the Times newspaper, which measures two feet by three. Indeed, till about 1825, the legislature restricted the size of newspapers to twenty-two by thirty-two inches, beyond which they could not be stamped; which restriction was done away with just as soon as it became possible to make by machinery any size of paper that might be desired. But, perhaps, in no department of paper-making has the advantage of the machine shone so conspicuously as in the paper used for paper-staining, and the consequent great reduction in price of the hangings. Before the application of the machine, the paper used by paper-stainers was of the size of twenty-eight by twenty-three inches, called elephant. It required, in order to form a piece of twelve lineal yards, that sixteen or eighteen of these sheets should be pasted together, which is now rendered wholly unnecessary by the paper being furnished to the stainers in sheets of twelve yards each in length.

The chief seats of paper manufacture in Great Britain are,—

1. Kent, where it was first established, and where there are a great number of hand-mills for making fine water-marked writing papers. There are also a good many machines for fine writing and printing paper.

2. In Hertfordshire, Buckinghamshire, and Oxfordshire, the manufacture of fine printing papers is very extensively carried on, and all made by machinery.

3. In Lancashire and the contiguous counties, it is carried on to a very large extent, the material, as already noticed, being chiefly derived from the refuse of the cotton mills, to which is added a mixture of cotton-bagging, of which there is a large supply, and which tends to strengthen the paper. This description of paper, however, both from the impurities which are inseparable from so very dirty a material as the sweepings of the cotton mills, and from its spongy soft texture, is very inferior to that which is made out of a sound strong rag, provided that the trituration of the stuff, already adverted to, be done in a proper manner.

4. In Scotland the manufacture is carried on to a large and rapidly increasing extent. From the ready communication with London, and other causes, both fine writing papers and others find a ready market there. Independently of the white paper, there is manufactured in all parts of the country a large quantity of brown paper, made from old ropes, &c.

Mr M'Culloch, in his Commercial Dictionary, supposes that there are about 700 paper mills in England, and from seventy to eighty in Scotland. The former must, however, be on an average on a much smaller scale than the Scotch mills; for whilst the duty produced in England in 1833 amounted to L.622,933, it amounted in Scotland, in the same year, to L.102,536; thus showing, that although the mills in England are about ten times as numerous as those in Scotland, the duty is only about six times as much.

Paper is considerably adulterated with plaster of Paris, sometimes to the amount of thirty per cent., for the purpose of gaining weight. This can easily be detected by burning a portion of a sheet, when the plaster will remain after combustion in an ashy whitish-coloured residuum. Brown paper is also often mixed up with a good deal of ochre or clay, the makers saying that it is for the purpose of giving it a nice brown colour, though it may be doubted whether it be not also with the intention of increasing the weight.

The following table, showing the strength of different kinds of paper, has been prepared from actual experiment. It denotes the number of pounds avoirdupois required to break a strip of paper two inches wide, both ends being secured above, and the weights attached to a small wooden roller, resting upon the strip of paper.

	Weight in Grains avoirdupois, of a Superficial Foot.	Weight in Pounds, supported by a strip two Inches broad.
Bank post, very thin writing paper, sized	65	23
Ditto unsized, but thinner	48	13
Thick writing paper, machine made,	139	42
Ditto ditto, made by hand,	143	60
Ditto drawing paper, machine made,	217	55
Newspaper, sized at the machine	113	39
Paper used for Scotch bank-notes	95	70
Strong cartridge-paper	135	64
Pink blotting-paper	90	10

PART I.—PAPER-MONEY.

tility of aper- oney.

We endeavoured to explain, in the fifth section of the article Money, the reasons why paper has been used as a substitute for coins in the ordinary transactions of society, and the principles on which its value is maintained. It is consequently unnecessary to enter at length, on this occasion, on either of these subjects; but, to facilitate the understanding of what is to follow, we may shortly observe, that the employment of paper as a medium of exchange is an obvious means resorted to by society for saving expense and facilitating payments. An individual or an association, in whose wealth and discretion the public have confidence, issues promissory notes, binding himself or themselves to pay certain sums on demand, or at some specified period after the date of the notes. And it is obvious, that so long as these notes are punctually paid when due, and are not issued in excess, their circulation, besides being a source of profit to the issuers, is a great public accommodation. The weight of 1000 sovereigns exceeds twenty-one pounds troy, so that to pay or receive a large sum in metal would be exceedingly inconvenient; while there would be a great risk from loss, as well as a heavy expense incurred in the conveyance of specie from place to place. But with paper this may be effected with extreme facility, and payments of the largest sums, and at the greatest distances, may be made with almost no inconvenience or expense. And while the interest of individuals is thus consulted by the introduction and use of paper, it is of the greatest service to the public. Its employment, and the various devices for the economizing of currency to which it has led, enable the business of a commercial country like England to be carried on with a *tenth part*, perhaps, of the gold and silver currency that would otherwise be necessary. The cheapest instruments by which exchanges can be effected are substituted in the place of the dearest; and, besides doing their work better, this substitution enables the society to employ the various sums they must otherwise have employed as money, as capital in industrious undertakings, by which the public wealth and comforts are largely augmented. Of the various means, whether by the introduction of machinery or otherwise, that have been devised for promoting the progress of wealth and civilization, it would not be easy to point out one better calculated to attain its end than the introduction of a properly organized paper-money.

Definition of paper-money.

But paper-money, like many other highly useful inventions, is liable to great abuse, and, if not issued on sound principles, may become the cause of much mischief. By paper-money we mean notes issued by individuals or associations, for certain sums, and made payable on demand, or when presented. This description of paper is known in this country by the name of bank-paper, or bank-notes, from its being issued only by bankers. Bills of exchange, or bills issued by bankers, merchants, or other individuals, and payable some time after date, perform, also, in some respects, the functions of money; and being transferred from individuals, make payments much in the same way as if they consisted of bank-notes for the same amount.

Distinction between paper-money or bank-notes and bills of exchange.

But though there are many points in which a bill of exchange and a bank-note closely resemble each other, there are others in which there is a distinct and material difference between them. A note bears to be payable on demand; it is not indorsed by a holder on his paying it away; the party receiving has no claim on the party from whom he received it, in the event of the failure of the issuers;[1] and every one is thus encouraged, reckoning on the facility of passing it to another, to accept bank-paper, "*even though he should doubt the ultimate solvency of the issuers.*"[2] Bills, on the contrary, are almost all drawn payable at some distant period; and those into whose hands they come, if they be not in want of money, prefer retaining them in their possession, in order to get the interest that accrues upon them. But the principal distinction between notes and bills is, that every individual, in passing a bill to another, has to indorse it, and by doing so makes himself responsible for its payment. "A bill circulates," says Mr Thornton, "in consequence chiefly of the confidence placed by each receiver of it in the last indorser, his own correspondent in trade; whereas the circulation of a bank-note is owing rather to the circumstance of the name of the issuer being so well known as to give it an universal credit."[3] Nothing, then, can be more inaccurate than to represent bills and notes in the same point of view. If A pay to B L.100 in satisfaction of a debt, there is an end of the transaction; but if A pay to B a bill of exchange for L.100, the transaction is not completed; and, in the event of the bill not being paid by the person on whom it is drawn, B will have recourse upon A for its value. It is clear, therefore, that a great deal more consideration is always required, and may be fairly presumed to be given, before any one accepts a bill of exchange in payment, than before he accepts a bank-note. The note is payable on the instant, without deduction—the bill not until some future period; the note may be passed to another without incurring any risk or responsibility, whereas every fresh issuer of the bill makes himself responsible for its value. Notes form the currency of all classes, not only of those who are, but also of those who are not, engaged in business, as women, children, labourers, &c. who in most instances are without the power to refuse them, and without the means of forming any correct conclusion as to the solvency of the issuers. Bills, on the other hand, pass only, with very few exceptions, among persons engaged in business, who are fully aware of the risk they run in taking them. There is plainly, therefore, a wide and obvious distinction between the two species of currency; and it cannot be fairly argued, that because government interferes to regulate the issue of the one, it should also regulate the issue of the other.

When, therefore, we speak of notes, or paper-money, we mean notes issued by banks, and payable on demand. And unless when the contrary is mentioned, it is to these only that the subjoined statements apply.

Regulations with respect to the issue of notes.

To obviate the endless inconveniences that would arise from the circulation of coins of every weight and degree of purity, were there no restrictions on their issue, all governments have forbidden the circulation of coins not of a certain specified or standard weight and fineness. And the recurrence of similar inconveniences from the issue of notes for varying sums, and payable under varying conditions, have led, in all countries in which paper-money is made use of, to the enacting of regulations forbidding the issue of notes below a certain amount, and laying down rules for their payment. In England at this moment no note payable to bearer on demand can be issued for less than five pounds, and they must all be paid the moment they are presented. In Scotland and Ireland the minimum value of bank-notes is fixed at one pound, the regulations as to payment being the same as in England. In order to preserve the monopoly of the London circulation to the Bank of England, no notes payable to bearer on demand are allowed to be issued by individuals or associations, other than the Bank of England, within sixty-five miles of St Paul's. But beyond these limits every one who complies with the above regulations as to the minimum amount of notes, and who promises to pay them on demand, may, on paying the stamp-duty, and making returns of the issues to the stamp-office, circulate any amount of notes they can succeed in getting the public to take off.

Regulations as to the issue of notes defective.

We think it might be safely inferred, even if we wanted experience of the actual working of a currency so issued, that a system like this must unavoidably lead to the greatest abuse. The public is very apt to be deceived, in the first instance, in giving confidence to or taking the paper of an individual or an association; and though that were not the case, the condition of the individual or company may subsequently change from bad or expensive management, improvident speculation, unavoidable losses, and fifty other things of which the public can know nothing, or nothing certain. The fact that any particular banker who issues paper enjoys the public confidence, is, at best, a presumption merely, and no proof that he really deserves it. The public believes him to be rich and discreet; but this is mere hypothesis; the circumstances which excite confidence at the outset, and which preserve it, are often very deceptive; and in the vast majority of instances the public has no certain knowledge, nor the means of obtaining any, as to the real state of the case. But it is unnecessary to argue this point speculatively. There have, unfortunately, been innumerable instances in which it has turned out that bankers who had long been in the highest credit, and whose notes had been unhesitatingly accepted by the public, have been found to be, on the occurrence of any thing to excite suspicion, quite unable to meet their engagements.

---

[1] Practically speaking, this is the fact; but a person paying away a bank-note is liable to be called upon for repayment should the bank fail before it was in the power of the party to whom it was paid, using ordinary diligence to present it. The responsibility seldom exceeds a couple of hours, and can hardly in any case exceed a couple of days. In practice it is never adverted to.

[2] Thornton on Paper Credit, p. 172.

[3] Ibid. p. 40.

The confining of the issue of notes to joint-stock associations would not give them additional security or value.

It has been supposed that the objections to the issue of notes on our present system, because of the risk of non-payment, might be obviated were they issued only by associations or joint-stock companies. But it is not easy to see on what principle leave should be granted to fifty or sixty individuals to do that which is to be denied to five or six. And though this difficulty were got over, the measure would not have the effect supposed. A single individual may possess more wealth than a number of individuals associated together; and the chances are, that if he engage in banking, or any other business, it will be better managed than by a company. Under our present system, and in fact it is impossible to prevent it under any system, the partners in joint stocks, as in other banks, may be men of straw, or persons without property, and unable to fulfil their engagements. It is of the essence of a secure and well-established paper currency, that the notes of which it consists should be of the exact value of the gold or silver they profess to represent, and that, consequently, they should be paid the moment they are presented. But it is not enough to order that this condition shall be uniformly complied with. Such order is obeyed only by the opulent, prudent, and conscientious banker, and forms little or no check on the proceedings of those of a contrary character. It is the latter class, however, that it is especially necessary to look after; and it is needless to say that any system that permits notes to be issued without let or hindrance by speculative, ignorant, or unprincipled adventurers, must be essentially vicious.

The issue of notes affords great temptation to, and facilities for, the commission of fraud.

The issue of notes is of all businesses that which seems to hold out the greatest prospect of success to the schemes of those who attempt to get rich by preying on the public. The cost of engraving and issuing notes is but an inconsiderable item compared with the sums for which they are issued; and provided they be got into any thing like extensive circulation, they become at once considerably productive. They are not issued, except, as explained in the article Money (sect. 5), on the deposit of bills or other securities, yielding a considerable rate of interest; so that if an individual, or set of individuals, with little or no capital, contrive, by fair appearances, promises, and similar devices, to insinuate himself or themselves into the public confidence, and can maintain L.20,000, L.50,000, or L.100,000 in circulation, he or they secure a good income in the mean time; and when the bubble bursts, and the imposture is detected, they are no worse off than when they set up their bank. On the contrary, the presumption is, that they are a great deal better off; and that they have taken care to provide, at the cost of the credulous and deceived public, a reserve stock for their future maintenance; hence, seeing the facilities for committing fraud are so very great, the propriety, or rather necessity, of providing against them.

Bank-paper substantially legal tender.

It has sometimes been contended, in vindication of our present system, that bank-notes are essentially private paper; that the accepting of them in payment is optional; and that as they may be rejected by every one who either suspects or dislikes them, there is no room or ground for interfering with their issue! But every body knows that, whatever notes may be in law, they are, in most parts of the country, practically and in fact, legal tender. The bulk of the people are totally without power to refuse them. The currency of many extensive districts consists in great part of country notes, and such small farmers or tradesmen as should decline taking them would be exposed to the greatest inconveniences. Every one makes use of, or is a dealer in, money. It is not employed by men of business only, but by persons living on fixed incomes, women, labourers, minors, and in short by every class of individuals, very many of whom are necessarily, from their situation in life, quite unable to form any estimate of the solidity of the different banks whose paper is in circulation. Such parties are uniformly severe sufferers by the failure of banks. The paper that comes into their hands is a part of the currency or money of the country, and it is quite as much a part of the duty of government to take measures that this paper shall be truly and substantially what it professes to be, as that it should take measures to prevent the issue of spurious coins, or the use of false or deficient weights and measures.

Security ought to be taken from the issuers of notes.

Now, it will be found, should the circulation of provincial notes be allowed to continue, that there is but one means of making sure of the solvency of the issuers, and of providing for their being paid when presented; and that is, by compelling all issuers of such notes to give security for their payment. This, and this only, will hinder the circulation of spurious paper, and afford a sufficient guarantee that the notes the public are obliged to take are really, and in fact, what they profess to be. The measure, too, is one that might be easily enforced. To carry it into effect, it would merely be necessary to order that all individuals or companies, on applying for stamps, should be obliged, previously to their obtaining them, to lodge in the hands of the commissioners an assignment to government stock, mortgages, landed or other fixed property, equivalent to the amount of the stamps issued to them, to be held in security for their payment.

It has been objected to this plan, that it would be injurious, by locking up a portion of the capital of the banks; but this is plainly an error. Its only effect in this respect would be to force such banks as issued notes to provide a supplemental capital, as a security over and above the capital required for conducting their business. But this supplemental capital would not be unproductive. If it consisted of lands, the owners would receive the rents; and if it consisted of government securities, they would receive the dividends or interest due upon them, precisely in the same way that they are received by other persons; while the fact being known that they possessed this supplemental capital, or that they had lodged security for the payment of their notes, would, by giving the public perfect confidence in their stability, enable them to conduct their business with a less supply of floating or immediately available capital than would otherwise be necessary.

It is absurd to object to this plan on the ground of its interfering with the private pursuits of individuals. It is the duty of government to interfere to regulate every business or pursuit that might otherwise become publicly injurious. On this principle it interferes to prevent the circulation of spurious coins, and of notes under a certain sum, and not payable on demand; and on the same principle it is called on to interfere to prevent the act ordering the payment of notes becoming again, as it has very frequently done already, a dead letter, by making sure that it shall be complied with. The interference that would take place under the proposed measure is not only highly expedient, but would be of the least vexatious kind imaginable. All that is required of the persons applying for stamps for notes is, that they should deposit in the hands of the commissioners a certain amount of exchequer bills, or other available securities, according to their demand for stamps. They are not asked to state how they mean to dispose of these stamps,—to whom or in what way they are to be issued. They are merely required to give a pledge that they shall be paid, or that they shall not be employed, as so many others have been, to deceive or defraud the public. It is little else than an abuse of language to call this an interference with private affairs.

The taking of security in the way now suggested, from the issuers of notes, would effectually provide for their payment when presented. Adventurers without capital, and sharpers anxious to get themselves indebted to the public, would find that banking was no longer a field on which they could advantageously enter. Notes would be made, in fact as well as in law, equivalent to the specie they profess to represent; and the paper currency would acquire a solidity of which it is at present wholly destitute.

The exacting of security from the issuers of paper would not obviate fluctuations in its amount and value, and would not, therefore, place the currency on a proper footing.

But though the plan of taking security would completely obviate the risk of loss from the circulation of worthless paper, or of paper issued by parties without the means, and probably also the inclination, to pay it on presentation, it would not touch another abuse inherent in the present system, that is, it would leave the currency exposed, as at present, to all those constantly recurring fluctuations in its amount—those alternations of glut and deficiency—by which it has been affected since provincial banks became considerably multiplied, and which are in the last degree injurious. A paper currency is not in a sound or wholesome state,—unless, 1*st*, means be taken to insure that each particular note or parcel of such currency be paid immediately on demand; and unless, 2*d*, *the whole currency vary in amount and value exactly as a metallic currency would do were the paper currency withdrawn and coins substituted in its stead.* The last condition is quite as indispensable to the existence of a well-established currency as the former; and it is one that cannot be realised otherwise than by confining the issue of paper to a single source.

All local issues of paper-money should be suppressed.

It is supposed by many, that there can be no greater fluctuations in a paper than in a metallic currency, provided the paper rest on an undoubted basis, and be regularly paid the moment it is presented. But this is an error. Wherever there are numerous issuers, there may be, and the chances are fifty to one there will be, perpetually recurring fluctuations in the amount and value of the currency. An over-issue of convertible paper is not, of course, indicated by any difference between the value of such paper and gold at home, but it is indicated by a fall of the exchange, and by an efflux of bullion to other countries. If paper were only issued by the Bank of England, or some one source in London, and then only in exchange for bullion, the currency would be in its most perfect state, and would fluctuate exactly as it would do were it wholly metallic. But at present it is quite otherwise. The currency is supplied by hundreds of individuals and associations, all actuated by different and frequently conflicting views and interests. The issues of the Bank of England, though not always, are generally governed by the state of the exchange, or rather by the influx and efflux of bullion, increasing when it flows into, and decreasing when it flows out of, the country. But it is quite otherwise with the provincial bankers. Their issues are not regulated by any such standard, but by the state of credit and prices in the districts in which they happen to be situated. If their managers suppose that these are good or improving, they rarely hesitate about making additional issues. Hence, when the state of the exchange, and the demand on the Bank of England for bullion, show that the currency is redundant, and ought to be contracted, the efforts of the Bank to effect its diminution are often impeded, and met by a contrary action on the part of the country banks. This is not owing to the ignorance of the latter. Under the supposed circumstances, the country bankers see, speaking generally, that they ought also to contract; but being a very numerous body, comprising several hundred establishments scattered over all parts of the country, each is impressed with the well-founded conviction, that all that he could do in the way of contraction would be next to imperceptible; and no one ever thinks of attempting it, so long as he feels satisfied of the stability of those with whom he deals. On the contrary, every banker knows, were he to withdraw a portion of his notes, that some of his competitors would most likely embrace the opportunity of filling up the vacuum so created; and that consequently he should lose a portion of his business, without in any degree lessening the amount of paper afloat. Hence, in nineteen out of twenty instances, the country banks go on increasing their aggregate issues long after the exchange has been notoriously against the country, and the Bank of England has been striving to pull up.

Issues of country bankers not dependent upon the exchange.

Efforts of the Bank of England to stop the efflux of bullion in 1836 counteracted by the country banks.

The circumstances now stated were strikingly exemplified in the course of 1836 and the early part of 1837. The excessive multiplication of joint-stock banks in 1836, the great additions they made to the number of notes afloat, and the still greater additions they made to the number of bills, checks, and other substitutes for money, occasioned a redundancy of the currency, a fall of the exchange, and a drain upon the Bank of England for gold. But while the latter was narrowing her issues, by supplying the exporters of bullion with gold in exchange for notes, the country banks went on increasing their issues! What the former did by contracting on the one hand, the latter more than undid by letting out on the other. The vacuum created by the withdrawal of Bank of England paper was immediately filled up, and made to overflow, by the issue of a more than equal amount of provincial paper; so that had it not been for the rise in the rate of interest, and the other repressive measures adopted by the Bank, the probability is, that she might have gone on paying away bullion for notes till she was drained of her last sixpence, without in any degree affecting the exchange. But this is not all. Not only do the country banks almost universally increase their issues when they ought to be diminished, but the moment they are compelled to set about their reduction, they run headlong into the opposite extreme, and unreasonable suspicion takes the place of blind unthinking confidence. The cry of *sauve qui peut* then becomes all but universal. It is seldom that a recoil takes place without destroying more or fewer of the provincial banks; and, provided the others succeed in securing themselves, little attention is usually paid to the interests of those they have taught to look to them for help. It may be worth while, in order to exhibit the truth of what has now been stated, shortly to advert to the destruction of country-bank paper in 1792–93, 1814, 1815, and 1816, 1825–26, and more recently in 1836–37.

Destruction of country banks and paper in 1792–93.

1. Previously to 1759 the Bank of England did not issue any notes for less than L.20; but having then commenced the issue of L.10 notes, her paper was gradually introduced into a wider circle, and the public became more habituated to its employment in their ordinary transactions. The distress and embarrassment that grew out of the American war proved exceedingly unfavourable to the formation of country banks, or of any establishments requiring unusual credit and confidence. No sooner, however, had peace been concluded, than everything assumed a new face. The agriculture, commerce, and still more the manufactures of the country, into which Watt and Arkwright's inventions had been lately introduced, immediately began to advance with a rapidity unknown at any former period. In consequence, that confidence which had either been destroyed or very much weakened by the disastrous events of the war was fully re-established. The extended transactions of the country required fresh facilities for carrying them on; and a bank was erected in every market-town, and almost in every village. The prudence, capital, and connections of those who set up these establishments

were but little attended to. The great object of a large class of traders was to obtain discounts; and the bankers of an inferior description were equally anxious to accommodate them. All sorts of paper were thus forced into circulation, and enjoyed nearly the same degree of esteem. The bankers, and those with whom they dealt, had the fullest confidence in each other. No one seemed to suspect that there was anything hollow or unsound in the system. Credit of every kind was strained to the utmost; and the available funds at the disposal of the bankers were reduced far below the level which the magnitude of their transactions required to render them secure.

The catastrophe which followed was such as might easily have been foreseen. The currency having become redundant, the exchanges took an unfavourable turn in the early part of 1792; a difficulty of obtaining pecuniary accommodation in London was not long after experienced; and notwithstanding the efforts of the Bank of England to mitigate the pressure, a violent revulsion took place in the latter part of 1792 and the beginning of 1793. The failure of one or two great houses excited a panic which proved fatal to many more. When this revulsion began, there were about three hundred and fifty country banks in England and Wales, of which about a hundred were compelled to stop payments, and upwards of fifty were totally destroyed, producing by their fall an extent of misery and bankruptcy till then unknown in England.

"In the general distress and dismay, every one looked upon his neighbour with caution, if not with suspicion. It was impossible to raise money upon the security of machinery, or shares of canals; for the value of such property seemed to be annihilated in the gloomy apprehension of the sinking state of the country, its commerce and manufactures; and those who had any money, not knowing where they could place it with safety, kept it unemployed and locked up in their coffers. Amid the general calamity, the country banks, which had multiplied greatly beyond the demand of the country for circulating paper currency, and whose *eagerness to push their notes into circulation* had laid the foundation of their own misfortunes, were among the greatest sufferers, and, consequently, among the greatest spreaders of ruin and distress among those connected with them; and they were also the chief cause of the drain of cash from the Bank of England, exceeding any demand of the kind for about ten years back. Of these banks above a hundred failed, whereof there were twelve in Yorkshire, seven in Northumberland, seven in Lincolnshire, six in Sussex, five in Lancashire, four in Northamptonshire, four in Somersetshire, &c."[1]

Attempts have sometimes been made to show that this crisis was not occasioned by an excess of paper-money having been forced into circulation, but by the agitation caused by the war then on the eve of breaking out. But there do not seem to be any good grounds for this opinion. The unerring symptoms of an overflow of paper—a fall of the exchange, and an efflux of bullion—took place early in 1792, or about twelve months before the breaking out of hostilities. Mr Chalmers states, that none of the great houses that failed during this crisis had sustained any damage from the war. The efforts of the country bankers to force their paper into circulation occasioned the redundancy of the currency, and it was on them, and on the country dealers and farmers dependent on them, that the storm principally fell.[2] It is of importance to remark, that the Bank of England had no notes for less than L.10 and the country banks for less than L.5 in circulation when the crisis of 1792–93 took place.

Destruction of country banks and paper in 1814, 1815, and 1816.

2. During the period from 1800 to 1813 the number of country banks had increased from about 400 to 922; and in consequence partly of this rapid increase, and partly of the suspension of cash payments at the Bank of England in 1797, and the issue of one-pound notes by that establishment and the country banks, the amount of paper afloat was vastly increased, particularly after 1808, when it sunk to a heavy discount as compared with bullion. Mr Wakefield, whose extensive employment in the management of estates in all parts of the country gave him the most favourable opportunities for acquiring correct information, stated to the agricultural committee of 1821, that "down to the year 1813 there were banks in almost all parts of England, forcing their paper into circulation at an enormous expense to themselves, and in most instances to their own ruin. There were bankers who gave commission, and who sent persons to the markets to take up the notes of other banks; these people were called money-changers, and commission was paid them." (Report, p. 213.) And among the various answers to the queries sent by the Board of Agriculture in 1816, to the most intelligent persons in different parts of the country, there is hardly one in which the excessive issue of country-bank paper is not particularly specified as one of the main causes of the unprecedented rise of rents and prices previously to 1814.

Influenced partly by this extraordinary increase of paper, and partly by deficient harvests and the exclusion of foreign supplies, the price of corn rose to an exorbitant height during the five years ending with 1813. But, owing partly to the luxuriant crop of that year, and partly and chiefly, perhaps, to the opening of the Dutch ports, and the renewed intercourse with the continent, prices sustained a very heavy fall in the latter part of 1813 and the beginning of 1814. And this fall, having produced a want of confidence and an alarm among the country bankers and their customers, occasioned such a destruction of country-bank paper as has not been paralleled except by the revulsion of 1825–26. In 1814, 1815, and 1816, no fewer than 240 country banks stopped payment, and eighty-nine commissions of bankruptcy were issued against these establishments, being at the rate of *one* commission against every *ten and a half* of the total number of banks licensed in 1813! This destruction of bank-paper is said to have produced an extent of wretchedness and misery never equalled in any European country by any similar catastrophe, except, perhaps, by the breaking up of the Mississippi scheme in France.

Destruction of country banks and paper in 1825–26.

3. The destruction of country paper during the period now referred to, by reducing the amount of the currency, raised its value in 1816 nearly to a par with the value of bullion, and enabled measures to be taken for reverting to cash payments at the Bank of England, which was effected by the act 59 Geo. III. cap. 78. But notwithstanding the ample experience that had been supplied by the occurrences of 1792–93 and 1814–16, of the mischievous consequences of the issue of paper by the country banks, and of their want of solidity, nothing whatever was done, when provision was made for returning to specie payments, to restrain their issues, or to place them on a better footing. The consequences of such improvidence were not long in manifesting themselves. The prices of corn and other agricultural products, which had been greatly depressed in consequence of abundant harvests, in 1820, 1821, and 1822, rallied in 1823; and the country bankers, true to their invariable practice on similar occasions, immediately began to enlarge their issues. It is unnecessary to inquire into the circumstances which conspired, along with the rise of prices, to promote the extraordinary rage for speculation exhibited in 1824 and 1825. It is sufficient

---

[1] Macpherson's Annals of Commerce, vol. iv. p. 266.

[2] Comparative Estimate, p. 226, ed. 1812.

to observe, that in consequence of their operation, confidence was very soon carried to the greatest height. It did not seem to be supposed that any scheme could be hazardous, much less wild or extravagant. The infatuation was such, that even the most considerate persons did not scruple to embark in the most visionary and absurd projects; while the extreme facility with which discounts were procured upon bills at very long dates, afforded the means of carrying on every sort of undertaking. The most worthless paper was readily negotiated. Many of the country bankers seemed, indeed, to have no object other than to get themselves indebted to the public. And such was the vigour and success of their efforts to force their paper into circulation, that the amount of it afloat in 1825 is estimated to have been nearly fifty per cent. greater than in 1823.

The consequences of this extravagant and unprincipled conduct are well known. The currency having become redundant, the exchange began to decline in the summer of 1824. But the directors of the Bank of England having entered, in the early part of that year, into an engagement with the government to pay off such holders of four per cent. stock as might dissent from its conversion into a three and a half per cent. stock, were obliged to advance a considerable sum on this account after the depression of the exchange. This tended to counteract the effect of the drain on the Bank for gold, and in consequence the London currency was not very materially diminished till September 1825. This reduction was accompanied by a repetition of the events of 1793, but on a larger and more magnificent scale, and with more destructive consequences. The country banks began to give way the moment they experienced a considerably increased difficulty of obtaining accommodation in London, and all confidence and credit were immediately at an end. Suspicion having awakened from her trance, there were no limits to the run. Paper was not carried to the banks to obtain gold, in the view of exporting it, as a mercantile adventure, to the Continent, but for the purpose of escaping the loss which it became obvious a large portion of the holders of country notes would have to sustain. The destruction of country paper was so sudden and extensive, that in less than six weeks above seventy banking establishments were swept off, and a vacuum was created in the currency which absorbed from eight to ten millions of additional issues by the Bank of England; at the same time that myriads of those private bills that had previously swelled the amount of the currency, and added to the machinery of speculation, were wholly destroyed.

Measures for establishing joint-stock banks in 1826. Inadequacy of these measures.

4. Notwithstanding nations are proverbially slow and reluctant learners, the events of 1825–26, taken in connection with those of the same sort that had previously occurred, produced a conviction of the necessity of taking some steps to improve the system of country banking in England. But we regret to have to add, that the measures adopted in this view were very far indeed from being effectual to their object. In 1708 a law had been passed limiting the number of partners in banking establishments to six. This law was now repealed; and it was enacted that banks with any number of partners might be established for the issue of notes anywhere beyond sixty-five miles from London; and that banks not issuing notes might be established in London itself with any number of partners. The circulation of notes for less than five pounds in England and Wales was at the same time forbidden.

Much benefit was expected, but without any sufficient reason, to arise from these measures. So long as every one is allowed to issue notes without check or control, a thousand devices may be fallen upon to insure the circulation of those that are most worthless. Besides, there is no foundation whatever for the supposition, that the mere fact of a bank consisting of fifty or a hundred, instead of five or ten partners, renders it more worthy of confidence, or is any security that it will be better managed. The probability seems, in fact, to be rather the other way. A few wealthy individuals engaged in banking, or any other sort of business, must, if they would protect themselves from ruin, pay unremitting attention to their concerns, and act in a discreet and cautious manner. But the partners and managers of a great joint-stock company act under no such direct and pressing responsibility. The former, indeed, seldom take the trouble to inquire carefully into the business of the company; and the responsibility of their managers is of a very different kind from that of an opulent individual whose fortune is answerable for every error and false step he may commit. The recent history of the Northern and Central Joint-Stock Bank, and of various other associations, sufficiently establishes the truth of what has now been stated. The fact that there is a number of partners in a joint-stock bank, and the consequent notion, that though its affairs were to get into disorder, some of them would be able to make good the claims upon it, tends to procure a circulation for the notes of these establishments to which they may be very little entitled. They in truth afford very great facilities for the perpetrating of fraud both upon the partners and the public. And even when best managed, and resting on an impregnable foundation, they may and *do* issue in excess; and thus produce those fluctuations in the amount and value of the currency that are everywhere most disastrous, but especially in a commercial country.

The prohibition of the issue of one-pound notes has gone far to shut up one of the most convenient channels by which the inferior class of country bankers formerly contrived to get their notes into circulation; but there are many other channels still open to them, and of these they have not failed to avail themselves. We have already seen that there were no notes for less than five pounds in circulation in 1792–93, and yet fully a third part of the country banks then in existence stopped payments! This is enough to show how little security can be expected from this limitation.

Progress of the joint-stock system.

Those who supposed that joint-stock banks would be immediately set on foot in all parts of England, were a good deal disappointed with the slowness with which they spread for some years after the act permitting their establishment was passed. The heavy losses occasioned by the downfall of most of the joint-stock projects set on foot in 1824 and 1825, made all projects of the same kind be looked upon for a considerable period with suspicion, and deterred most persons from embarking in them. But this prejudice gradually wore off; and the increasing prosperity of the country, and the difficulty of vesting money so as to obtain from it a reasonable return, generated of new a disposition to adventure in hazardous projects. A mania for embarking in speculative schemes acquired considerable strength in 1835, and during the first six months of 1836 it raged with a violence but little inferior to that of 1825. It was at first principally directed to railroad projects; but it soon began to embrace all sorts of schemes, and, among others, joint-stock banks, of which an unprecedented number were projected in the course of the year. The progress of the system has been as follows:

	Banks.		Banks.
In 1826 there were registered	3	In 1832 there were registered	7
In 1827	4	In 1833	9
In 1828	0	In 1834	10
In 1829	7	In 1835	9
In 1830	1	In 1836	45
In 1831	9	Total	104

In point of fact, however, the number of banks created in 1836 was vastly greater than appears from this statement. We believe that, at an average, each of the forty-five banks established in that year, like those previously established, has from five to six branches; and as these branches transact all sorts of banking business, and enjoy the same credit as the parent establishment, from which they are frequently at a great distance, they are, to all intents and purposes, so many new banks; so that, instead of forty-five, it may safely be affirmed that about *two hundred* new joint-stock banks were opened in England and Wales in 1836, and mostly in the first six months of that year!

Over-issue by the joint-stock banks in 1836.

In January, February, and March 1836, when the rage for establishing joint-stock banks was at its height, the exchange was either at par, or but slightly in our favour, showing that the currency was already up to its level, and that if any considerable additions were made to it, the exchange would be depressed, and a drain for bullion be experienced. But these circumstances, if ever they occurred to the managers of the joint-stock banks, do not seem to have had, and could not in truth be expected to have, the least influence over their proceedings. Their issues, which amounted on the 26th of December 1835 to L.2,799,551, amounted on the 25th of June to L.3,588,064, exclusive of the vast mass of additional bills, checks, and other substitutes for money they had put into circulation. The consequences were such as every man of sense must have foreseen. In April 1836 the exchange became unfavourable, and bullion began to be demanded from the Bank of England. The latter, that she might the better meet the drain, raised the rate of interest in June from four to four and a half per cent., and this not being sufficient to lessen the pressure on her for discounts, she raised it in August from four and a half to five per cent. But during the whole of this period the country banks went on increasing their issues. We have already seen that, on the 25th of June 1836, their issues were L.788,513 greater than they had been on the preceding 26th of December; and notwithstanding the continued drain for bullion, and the rise in the rate of interest by the Bank of England in June and August, and the reduction of her issues, the issues of the joint-stock banks increased from L.3,588,064 in June, to no less than L.4,258,197 on the 31st of December, being an increase of nearly twenty per cent. after the exchange was notoriously against the country; and the most serious consequences were apprehended from the continued drain for bullion on the Bank of England!

It may perhaps be imagined that the increased issue of the joint-stock banks would be balanced by a corresponding diminution of the issues of the private banks, and that on the whole the amount of their joint issues might not be increased. This, however, was not the case. Some private banks were abandoned in 1836, and others incorporated with joint-stock banks; and it is farther true, that those which went on managed their affairs with more discretion than their associated competitors. But, from the 26th of September 1835 to the 31st of December 1836, the issues of the private banks were diminished only L.159,087, whilst those of the joint stocks were increased during the same period L.1,750,160, or more than *ten times* the falling off in the others!

easons hy there hould be nly *one* suer of aper-oney.

These statements show conclusively the extreme inexpediency of having more than one issuer of paper. Its issue ought in all cases to be governed exclusively by the state of the exchange, or rather, as already stated, by the influx and efflux of bullion. But the provincial banks may go on over-issuing for a lengthened period without being affected by a demand for bullion, or even for Bank of England paper. A drain for bullion always operates in the first instance on the Bank of England; and were she the sole issuer, she might always check the drain at the outset, by narrowing her issues, or by ceasing to replace the notes brought to her in exchange for bullion. But the country banks, not being immediately or speedily affected by the drain, take no steps to get rid of that redundancy of the currency by which it is occasioned; and, provided their credit be good, they may and *do* frequently go on for a lengthened period adding to their issues, and aggravating all the bad symptoms in the state of the currency. Thus we have seen the joint-stock banks in the early part of 1836 making large additions to their issues when the currency was already quite full; and, not stopping there, we have next seen them persisting, for more than six months, in increasing their issues in the teeth of a heavy and continued drain for bullion, a rapid rise in the rate of interest, and great apprehensions in the public mind. This conduct has nothing to do with the solidity of the banks. There is no reason whatever to think, supposing they had *all* given security for their issues, they would have been in any degree diminished. On the contrary, the probability is, that by putting an end to every doubt as to their stability, it would have materially facilitated their issues, and tempted them to increase them to a still greater extent.

But, in the end, an efflux of bullion is sure, by rendering money and all sorts of pecuniary accommodation scarce in the metropolis, to affect the country banks as well as the Bank of England; and then the shock given to industry, and the derangement of prices and transactions of all sorts, is severe in proportion to the previous over-issue. A revulsion of this sort seldom occurs without destroying some of the provincial banks, and exciting a panic, as was the case in 1792–93, and in 1825–26. But even when this is not the case, the check given to the practice of discounting, and the withdrawal of their accustomed accommodations from vast numbers of individuals, necessarily occasion a great deal of inconvenience and distress. The Bank of England, by bolstering up the Northern and Central Bank in November 1836, averted the bankruptcy of that establishment, which had no fewer than *forty* branches, and by doing so prevented the occurrence of a panic, and a run that would most likely have proved fatal to many other joint-stock and private banks. Still, however, the shock given to all sorts of industrious undertakings, by the revulsion in the latter part of 1836, although unaccompanied with any panic, was very severe. All sorts of commercial speculations were for a while completely paralysed, and there were but few districts in which great numbers of individuals were not thrown out of employment. In Paisley, Birmingham, and various other towns, the distress occasioned by the revulsion was very general and long-continued. The following memorial, subscribed by all the leading manufacturers, merchants, and traders of Birmingham, was presented to Lord Melbourne in March 1837. It sets the disastrous influence of fluctuations in the amount and value of the currency in a very striking light.

"My Lord,—We, the undersigned merchants, manufacturers, and other inhabitants of the town of Birmingham, beg leave respectfully to submit to your Lordship the following facts:—1. During the last two or three years a very great improvement has taken place in the trade and commerce of the town and neighbourhood. The workmen have generally been placed in a condition of full employment and good wages, producing a general state of satisfaction and contentment among them. Their employers also have enjoyed a condition of ease and security which might be called affluence when compared with the losses, difficulties, and anxieties which they endured for several years before. No stock of goods was accumulated, no overtrading of any kind existed; the products of one man's industry were readily exchanged for those of another; and all the products of industry in every trade were carried off into the absolute consumption of the people quite as fast as they could be produced.

"2. Suddenly within the last three months, with all the elements of general prosperity remaining unimpaired, this gratifying state of things has disappeared, and has been succeeded by a general state of difficulty and embarrassment, threatening the most alarming consequences to all classes of the community. Orders for goods are countermanded and discontinued, both for the foreign and home trade.

"The prices of goods are falling, so as in many cases to occasion a loss instead of a profit on their production. The process of production is thus obstructed; the workmen are beginning to be discharged, or to be placed upon short employment; and we are confident, that unless remedial measures be immediately applied, a large proportion of our population will shortly be thrown entirely out of employment.

"3. We earnestly solicit the serious and immediate attention of his majesty's government to this alarming state of things, confidently hoping that they will forthwith adopt decisive and effectual measures for its relief."

Certainly the legislature will most strangely neglect its duty, if it allow a system productive of such fatal consequences to continue to spread its roots and scatter its seeds on all sides. As long as any individual, or set of individuals, may usurp the royal prerogative, and issue money without let or hindrance, so long will it be issued in excess in periods when prices are rising and confidence high, and be suddenly and improperly withdrawn when prices are falling and confidence shaken. All the causes of fluctuation inherent in the nature of industry are aggravated a thousandfold by this vicious system, at the same time that it brings many new ones into existence. There is not, in fact, any reason for supposing, that if our currency had been either metallic, or made to fluctuate exactly as it would have done had it been metallic, that the difficulties in which we were involved in 1836 and 1837 would ever have been heard of. The inordinate increase of banks, of money, and of the facilities for obtaining money, in the spring of 1836, contributed powerfully to the rapid and uncalled-for increase of prices, the multiplication of wild and absurd projects, and the excess of confidence which distinguished that period; at the same time that, by bringing on a fall of the exchange and a drain for bullion, they insured the subsequent revulsion. If it be wished that the country should be kept for ever under an intermittent fever—now suffering from a hot and then from a cold fit, now in an unnatural state of excitement, leading to, and necessarily ending in, an unnatural state of depression—the present money system is the best possible. But we believe the reader will agree with us in thinking, that a fever of this sort is not more injurious to the animal than to the political body. So dangerous a disorder is not to be trifled or tampered with. This is not a case in which palliatives and anodynes can be of any real service. If a radical cure be not effected, it will go far to paralyse and destroy the patient.

Now, to accomplish this radical cure, that is, to make sure that *the fluctuations of the currency shall not exceed those which would occur were it wholly metallic*, it is indispensable, as already stated, that all local notes should be suppressed, and the issue of paper confined entirely to one body.

The exacting of security previously to the issue of notes would guarantee the holders from loss, and be in so far advantageous; but it would not hinder that competition among the issuers that is so very injurious, nor prevent the supply of paper being at one time in excess, and at another deficient. If we would provide for that unity of action and that equality of value that are so indispensable, we must make an end of a plurality of issuers. If one body only were intrusted with the issue of notes, it would be able immediately to narrow the currency when bullion began to be exported, and to expand it when it began to be imported; and it would be easy for the legislature to lay down and enforce such regulations as would effectually prevent the fluctuations in the amount and value of the currency ever exceeding those that would take place if it consisted wholly of the precious metals. But nothing of the sort need be attempted, so long as it is supplied by more than one source. Every thing must then be left to the discretion of the parties. And it will certainly happen in time to come, as it has invariably happened in time past, that some of them will be increasing their issues when they should be diminished, and diminishing them when they should be increased.

Mr S. J. Loyd, whose authority on all questions of this sort is so deservedly high, states distinctly, that "an adherence to sound principle would certainly lead to the conclusion, that the issues of paper-money should be confined to *one body, intrusted with full power and control over the issues, and made exclusively responsible for the due regulation of their amount*."[1] He is, however, disposed to think that the practice in this country, of individuals and associations issuing notes, has been so long established, and become so intimately connected with the habits and prejudices of the people, as to leave but little hope of its eradication. We do not, however, think that the difficulties in the way of the suppression of local notes would be found to be nearly so great were it set seriously about, as Mr Loyd seems to infer. Were parliament to enact that all local or provincial notes payable on demand in England and Wales should cease to circulate some two or three years hence, their withdrawal might, we apprehend, be effected with very little trouble and inconvenience. The circulation of notes, now that those for less than L.5 have been suppressed, is far from being one of the principal sources of banking profits. The stamp-duty, the expense of engraving, and the still heavier expense necessary to keep notes afloat, and to provide for their payment when they may happen to be presented, cut deep into the profits made by their issue. Our readers are no doubt generally aware that several country banks have, within the half dozen years ending with 1837, withdrawn their own notes from circulation, and issued in their stead those of the Bank of England, according to certain terms agreed on with the latter. The banks in question would not certainly have done this had it made any serious inroad on their profits. But it has not sensibly diminished them; and the proof of this is, that the banks which have made this arrangement realise quite as large profits as are realised by those that continue to issue notes of their own. We submit that this is decisive of the whole question. It proves that the profits of the provincial banks are not sensibly impaired by the substitution for their own, of Bank of England notes. Had the project for suppressing local notes been productive of any considerable loss to the issuers, it would have furnished a plausible, though by no means a valid, argument against it; for it would be contradictory and absurd to pretend that any set of persons can be entitled permanently to enjoy a privilege injurious to the community. But there is no room nor ground even for an appeal *ad mi-*

---

[1] Reflections on the Pamphlet of Mr Horsley Palmer, p. 52.

sericordiam on the part of the private issuers. The fact that numbers of them have spontaneously, and without solicitation of any kind, abandoned the privilege of issue, and replaced their own notes with those of the central issuer in London, shows conclusively that the privilege in question is worth little or nothing, and, consequently, that it may be withdrawn without entailing any considerable hardship on any one. It is essential to the placing of the currency on a proper footing, that all local notes should be suppressed; and as their suppression would not be injurious to the issuers, what possible reason can be alleged for continuing their circulation?

Mode in which a single issuer of paper should act so as to make the amount and value of the currency vary exactly as if it were metallic.

We have said that it would be easy, were there only one issuer, to enforce compliance with such rules and regulations as would make the amount and value of the currency vary at all times exactly as if it were metallic. This has been doubted; but nothing could be more facile. Suppose that all local notes are withdrawn, and that there is only one issuer of paper; all that would be necessary to maintain an identity of amount and value between gold and paper would be, to regulate the currency exclusively by the influx and efflux of bullion; that is, never to issue an additional note except it be paid away for an equivalent amount of bullion brought to the office, nor to withdraw a note except when it is received in payment of an equivalent amount of bullion demanded from the office. The business of such an office would be entirely routine. Its managers would have no sort of discretion; their duty being merely to give paper for gold and gold for paper, according to the demands of the public. It has been frequently objected to the establishment of a national bank, that it would become a focus of intrigue and jobbing, and would be prostituted, or supposed to be prostituted, for the advancement of mere party purposes; and this, no doubt, would be the case were it allowed to discount and to transact ordinary banking business. A national bank for such purposes would be a national nuisance, that would very soon require to be abated. But were it confined, as it should be, to the mere issue of paper on the principle and in the way now stated, it could not be perverted to any sort of sinister object. Its conductors would be restricted to a sort of mill-horse path, and it would be impossible for them, even if so disposed, to show favour or partiality to any one. All would depend on an invariable rule; and the amount and value of the paper afloat would never exceed nor fall short of the amount and value of the bullion that would circulate in its stead were it withdrawn.

Supposing the average amount of paper afloat with a single issuer to be from thirty to forty millions, a stock of ten or twelve millions of bullion would be more than sufficient to begin with; for, it is hardly possible to imagine, under such a system, that any thing should ever occur to lessen the paper currency so much as twenty per cent., or consequently to occasion a demand for so much as six or eight millions of bullion.

rinciple n which e Bank f England deavours govern r issues: ounter-ting a-ncies to hich she ust at-nd.

The Bank of England has endeavoured, for a considerable number of years past, to govern her issues nearly in the way now pointed out. But, in her present situation, having her operations frequently counteracted by other issuers, she neither can nor ought always to regulate her conduct by a regard to strict principle. She must look to the proceedings of others, by which she may be deeply compromised; and she must not only consider what may be the effect of the measures she may adopt on the exchange, or on the influx and efflux of bullion, but how they may be regarded by the provincial banks, and expected to influence them. Hence the Bank may frequently be justified in narrowing her issues when, had she been the sole issuer, she ought to have increased them, and conversely. But it is needless to say that this is a most unsatisfactory state of things, both as respects the Bank and the country. The former is obliged to exercise a discretion which cannot be safely confided to any set of individuals, whilst the latter is sure to suffer from all the errors into which the directors may fall, as well as from the disastrous consequences resulting from that competition of rival and conflicting issues, against which no degree of intelligence on the part of the directors of the Bank of England can possibly guard. In fact, we have no idea that it will be practicable for the latter and the country banks to go on together on their present footing. As matters now stand, the Bank of England may be brought at any time, and frequently is brought, into the greatest jeopardy by the proceedings of parties over whom she has no sort of control. The over-issue of the provincial banks, by depressing the exchange, drains the Bank of gold; and then their discredit, and perhaps failure, may, by exciting a panic, bring her to a stand still! Provided banks of deposit be established on sound principles, there cannot be too many of them. But it is quite otherwise with banks of issue. The more they are multiplied, the greater is the chance of fluctuation in their issues, and consequently in prices, credit, and so forth. Had the Bank of England been the sole issuer of paper, the crashes of 1792–93 and of 1825–26, and the revulsion of 1836–37, would not have occurred. They grew entirely out of the competition and proceedings of the provincial banks, and are in no degree whatever ascribable to anything else, domestic or foreign.

According to existing arrangements, the charter of the Bank of England must continue on its present footing till 1845. But we have no doubt, that were parliament to set about suppressing local issues,—an improvement that must precede every other,—the Bank would readily concur in any arrangement by which the proper regulation of her issues might be provided for and secured. But the suppression of local paper is indispensable as a preliminary to pave the way for other measures. Fluctuations in its amount and value are of the essence of a currency supplied by different issuers. If the country continue to tolerate the latter, it will unavoidably continue to suffer the perpetual recurrence of the former.

PART II.—BANKS.

Classes of banks.

Banks are commonly divided into banks of deposit and banks of issue; that is, banks that take care of other people's money, and banks that issue money of their own. But there are very few banks of issue that are not at the same time banks of deposit. This class of banks, as they exist in this and most other countries, are places where the money of individuals is received in deposit, payments being also made on their account, and loans made to the public. The managers of such banks are sometimes accustomed, as in most parts of England and Scotland, to pay interest at about one or two per cent. under the market rate for the money deposited in their hands; but when the business to be transacted in the receipt and payment of money on account of depositors is very large, it is not the practice for bankers, unless the deposits be proportionally great, to allow interest. The latter is the case in London. It is there customary for merchants and other people to send all the bills and drafts payable to them to their bankers, who make themselves responsible for their regular presentation for payment, and for their noting if not paid; and it is there also the practice to make all considerable payments by checks on bankers. Banking business is conducted in London at a heavy expense, and no little risk; and the

London bankers do not, therefore, except in special cases, allow interest on deposits. They are in the habit of stipulating, in order to indemnify themselves for their trouble and outlay, that the individuals dealing with them should keep an average balance of cash in their hands, varying according to the amount of business transacted on their account. The bankers then estimate, as well as they can, the amount of cash they must keep in their coffers to meet the probable demands of their customers, and employ the balance in discounting mercantile bills, in the purchase of government securities, or in some other sort of profitable adventure; so that their profits consist of the sum they realize upon such parts of the money lodged in their hands as they are able to employ in an advantageous way, after deducting the various expenses attendant on the management of their establishments. A bank of deposit would never be established if it had to depend on its own capital. It makes no profit, in its capacity of bank, till it begins to employ the capital of others.

Introduction and growth of private banking.

The business of banking was not introduced into London till the seventeenth century. It was at first conducted by the goldsmiths, who borrowed money from their customers at a certain rate of interest, and lent it to government and to private individuals at a higher rate. In the course of time, the business came to be conducted by houses who confined themselves to it only, and nearly in the mode in which we now find it. From 1708, as already stated, down to 1826, with the exception of the Bank of England, no company with more than six partners could be established, either in London or anywhere else in England and Wales, for conducting banking business; and by far the largest portion of that business is still conducted in the metropolis by firms with a small number of partners, or by what are called private banks.

Clearing house.

In 1775, the London, or rather the "city" bankers, established the "clearing house." This is a house to which each banker who deals with it is in the habit of daily sending a clerk, who carries with him the various bills and checks in the possession of his house that are drawn upon other bankers; and having exchanged them for the bills and checks in the possession of those others that are drawn upon his constituents, the balance on the one side or the other is paid in cash or Bank of England notes. By this contrivance the bankers connected with the clearing house are enabled to settle transactions to the extent of several millions a day, by the employment of not more, at an average, than from L.200,000 to L.500,000 cash, or Bank of England notes.

Regulations to which banks for deposit only should be subjected.

The security afforded by a bank of deposit is a matter as to which there must always be more or less of doubt. When, indeed, a banking company confines itself to its proper business, and does not embark in speculations of unusual hazard, or from which its funds cannot be easily withdrawn, in the event of any sudden run or demand, it can hardly ever fail of being in a situation to meet its engagements; whilst the large private fortunes that most commonly belong to the partners afford those who deal with it an additional guarantee. Much, however, depends on the character of the parties, and on a variety of circumstances with respect to which the public can never be correctly informed; so that though there can be no doubt that the security afforded by many private banks of deposit is of the most unexceptionable description, this may not be the case with others.

All joint-stock banks, or banks having more than six partners, whether for deposit and issue, or for deposit merely, are ordered, by the act 3 and 4 Will. IV. cap. 83, to send quarterly returns of the number and names of their partners to the stamp-office. We see no good reason why similar returns should not, and several why they should, be required from *all* banks; and provided means were adopted for the proper publication of such returns, so that everybody might know with whom they were dealing, but little if any farther information would be required with banks not issuing notes. There is in this respect a wide difference between them and banks of issue. It is the duty of the government to take care that the value of the currency shall be as invariable as possible; but it has never been pretended that it is any part whatever of its duty to inquire into the security given by the borrowers to the lenders of money, any more than into the security given by the borrowers to the lenders of any thing else. Government very properly obliges a goldsmith to have his goods stamped, this being a security to the public that they shall not be imposed on in buying articles of the quality of which they are generally ignorant; but it does not require that the persons to whom the goldsmith sells or lends his goods should give him a guarantee for their payment. This is a matter as to which individuals are fully competent to judge for themselves; and there neither is nor can be any reason why a lender or depositor of bullion or notes should be more protected than a lender or depositor of timber, coal, or sugar. Gold being the standard or measure of value, government is bound to take effectual precautions that the currency shall truly correspond in the whole and in all its parts with that standard,—that every pound note shall be worth a sovereign, and that the amount and value of the aggregate notes in circulation shall vary exactly as a gold currency would do were it substituted in their stead. But this is all that government is called upon to do. If A trust a sum of money in the hands of B, it is their affair, and concerns no one else. Provided the money afloat correspond with the standard, it is of no importance, in a public point of view, into whose hands it may come. The bankruptcy of a deposit bank, like that of a private gentleman who has borrowed largely, may be productive of much loss or inconvenience to its creditors. But if the paper in circulation be equivalent to gold, such bankruptcies cannot affect either the quantity or value of money; and are, therefore, injurious only to the parties concerned.

Establishment and history of the Bank of England.

The Bank of England, which has long been the principal bank of deposit and circulation, not in this country only, but in Europe, was founded in 1694. Its principal projector was Mr William Paterson, an enterprising and intelligent Scotch gentleman, who was afterwards engaged in the ill-fated colony at Darien. Government being at the time much distressed for want of money, partly from the defects and abuses in the system of taxation, and partly from the difficulty of borrowing, because of the supposed instability of the revolutionary establishment, the Bank grew out of a loan of L.1,200,000 for the public service. The subscribers, besides receiving eight per cent. on the sum advanced as interest, and L.4000 a year as the expense of management, in all L.100,000 a year, were incorporated into a society denominated the Governor and Company of the Bank of England. The charter is dated the 27th of July 1694. It declares, amongst other things, that they shall "be capable, in law, to purchase, enjoy, and retain to them and their successors, any monies, lands, rents, tenements, and possessions whatsoever; and to purchase and acquire all sorts of goods and chattels whatsoever, wherein they are not restrained by act of parliament; and also to grant, demise, and dispose of the same.

"That the management and government of the corporation be committed to the governor and twenty-four directors, who shall be elected between the 25th of March and the 25th day of April each year, from among the members of the company duly qualified.

"That no dividend shall at any time be made by the said governor and company, save only out of the interest, profit, or produce arising by or out of the said capital stock or fund, or by such dealing as is allowed by act of parliament.

"They must be natural-born subjects of England, or naturalized subjects; they shall have in their own name, and for their own use, severally, viz. the governor at least L.4000, the deputy-governor L.3000, and each director L.2000, of the capital stock of the said corporation.

"That thirteen or more of the said governors and directors (of which the governor or deputy-governor must be always one) shall constitute a court of directors, for the management of the affairs of the company, and for the appointment of all agents and servants which may be necessary, paying them such salaries as they may consider reasonable.

"Every elector must have, in his own name and for his own use, L.500 or more capital stock, and can only give one vote. He must, if required by any member present, take the oath of stock, or the declaration of stock in case he be one of the people called Quakers.

"Four general courts to be held in every year, in the months of September, December, April, and July. A general court may be summoned at any time, upon the requisition of nine proprietors duly qualified as electors.

"The majority of electors in general courts have the power to make and constitute by-laws and ordinances for the government of the corporation, provided that such by-laws and ordinances be not repugnant to the laws of the kingdom, and be confirmed and approved, according to the statutes in such case made and provided."

The corporation is prohibited from engaging in any sort of commercial undertaking other than dealing in bills of exchange, and in gold and silver. It is authorized to advance money upon the security of goods or merchandise pledged to it; and to sell by public auction such goods as are not redeemed within a specified time.

It was also enacted, in the same year in which the Bank was established, by statute 6 William and Mary, c. 20, that the Bank, "shall not deal in any goods, wares, or merchandise (except bullion), or purchase any lands or revenues belonging to the crown, or advance or lend to their majesties, their heirs or successors, any sum or sums of money, by way of loan or anticipation, or any part or parts, branch or branches, fund or funds, of the revenue, now granted or belonging, or hereafter to be granted, to their majesties, their heirs and successors, other than such fund or funds, part or parts, branch or branches, of the said revenue only, on which a credit of loan is or shall be granted by parliament." And in 1697 it was enacted, that the "common capital or principal stock, and also the real fund, of the governor and company, or any profit or produce to be made thereof, or arising thereby, shall be exempted from any rates, taxes, assessments, or impositions whatsoever, during the continuance of the Bank; that all the profit, benefit, and advantage from time to time arising out of the management of the said corporation, shall be applied to the uses of all the members of the said association of the governor and company of the Bank of England, rateably and in proportion to each member's part, share, and interest in the common capital and principal stock of the said governor and company hereby established."

In 1696, during the great recoinage, the Bank was involved in great difficulties, and was even compelled to suspend payment of her notes, which were at a heavy discount. Owing, however, to the judicious conduct of the directors, and the assistance of the government, the Bank got over the crisis. But it was at the same time judged expedient, in order to place her in a situation the better to withstand any adverse circumstances that might afterwards occur, to increase her capital from L.1,200,000 to L.2,201,171. In 1708, the directors undertook to pay off and cancel one million and a half of exchequer bills they had circulating two years before, at four and a half per cent., with the interest upon them, amounting in all to L.1,775,028, which increased the permanent debt due by the public to the Bank, including L.400,000 then advanced in consideration of the renewal of the charter, to L.3,375,028, for which they were allowed six per cent. The bank capital was then also doubled, or increased to L.4,402,343. But the year 1708 is chiefly memorable, in the history of the Bank, for the act previously alluded to, which declared, that during the continuance of the corporation of the Bank of England, "it should not be lawful for any body politic, erected or to be erected, other than the said governor and company of the Bank of England, or of any other persons whatsoever, united or to be united in covenants or partnership, exceeding the number of six persons, in that part of Great Britain called England, to borrow, owe, or take up any sum or sums of money on their bills or notes payable on demand, or in any less time than six months from the borrowing thereof." This proviso, which has had so powerful an operation on banking in England, is said to have been elicited by the Mine-Adventure Company having commenced banking business, and begun to issue notes.

The charter of the Bank of England, when first granted, was to continue for eleven years certain, or till a year's notice after the 1st of August 1705. The charter was further prolonged in 1697. In 1708, the Bank having advanced L.400,000 for the public service, without interest, the exclusive privileges of the corporation were prolonged till 1733. And in consequence of various advances made at different times, the exclusive privileges of the Bank have been continued by successive renewals, till a year's notice after the 1st of August 1855, under the proviso that they may be cancelled on a year's notice to that effect being given on the 1st of August 1845.

Renewals of Bank charter, with the conditions.

We subjoin an account of the successive renewals of the charter, of the conditions under which these renewals were made, and of the variations in the amount and interest of the permanent debt due by government to the Bank, exclusive of the dead weight.

Date of Renewal.	Conditions under which Renewals were made, and Permanent Debt contracted.	Permanent Debt.		
		L.	s.	d.
1694	Charter granted under the act 5 and 6 Will. III. c. 20, redeemable upon the expiration of twelve months' notice after the 1st August 1705, upon payment by the public to the Bank, of the demand therein specified. Under this act the Bank advanced to the public L.1,200,000 in consideration of their receiving an annuity of L.100,000 a year, viz. eight per cent. interest, and L.4000 for management..............................	1,200,000	0	0
1697	Charter continued by 8 and 9 Will. III. c. 20, till twelve months' notice after 1st of August 1710, on payment, &c. Under this act the Bank took up and added to their stock L.1,001,171 exchequer bills and tallies.			
1708	Charter continued by 7 Anne, c. 7, till twelve months' notice after 1st of August 1732, on payment, &c. Under this act the Bank advanced L.400,000 to government without interest; and delivered up to be cancelled L.1,775,027. 17s. 10d. exche-

	Under this act the Bank advanced to government L.3,000,000 for six years without interest; but in pursuance of the recommendation of the committee of 1807, the advance was continued, without interest, till six months after the signature of a definitive treaty of peace.			
	In 1816, the Bank, under authority of the act 56 Geo. III. c. 96, advanced at three per cent., to be repaid on or before the 1st of August 1833..........	3,000,000	0	0
1833	Charter continued by 3 and 4 Will. IV. c. 98, till twelve months' notice after the 1st of August 1855, with a proviso that it may be dissolved on twelve months' notice after the 1st of August 1845, on payment, &c.	14,686,000	0	0
	This act directs that in future the Bank shall deduct L.120,000 a year from their charge on account of the management of the public debt; and that a fourth part of the debt due by the public to the Bank, or L.3,638,250, be paid off..................................	3,638,250	0	0
	Permanent advance by the Bank to the public, bearing interest at three per cent., independent of the advances on account of dead weight, or other public securities held by her...	11,047,750	0	0

For further details as to this subject, see the appendix, No. 1, of the Report of 1832 on the Renewal of the Bank Charter, and the acts of parliament referred to in it. See also James Postlethwayt's History of the Revenue, pp. 301–310; and Fairman on the Funds, seventh edition, pp. 85–88, &c.

The capital of the Bank on which dividends are paid has never exactly coincided with, though it has seldom differed very materially from, the permanent advance by the Bank to the public. We have already seen that it amounted in 1708 to L.4,402,243. Between that year and 1727 it had increased to near L.9,000,000. In 1746 it amounted to L.10,780,000. From this period it underwent no change till 1782, when it was increased eight per cent., or to L.11,642,400. It continued stationary at this sum down to 1816, when it was raised to L.14,553,000, by an addition of twenty-five per cent. from the profits of the Bank, under the provisions of the act 56 Geo. III. c. 96. The act for the renewal of the charter 34 Will. IV. c. 98, directed that the sum of L.3,638,250, the portion of debt due to the Bank to be repaid by the public, should be deducted from the Bank's capital; which, in consequence, is now L.10,914,750. (*Report on Bank Charter*, Appen. No. 33.)

Runs upon the Bank.

The Bank of England has been frequently affected by panics amongst the holders of her notes. In 1745 the alarm occasioned by the advance of the Highlanders, under the Pretender, as far as Derby, led to a run upon the Bank; and in order to gain time to effect measures for averting the run, the directors adopted the device of paying in shillings and sixpences! But they derived a more effectual relief from the retreat of the Highlanders, and from a resolution agreed to at a meeting of the principal merchants and traders of the city, and very numerously signed, declaring the willingness of the subscribers to receive bank-notes in payment of any sum that might be due to them, and pledging themselves to use their utmost endeavours to make all their payments in the same medium.

During the tremendous riots in June 1780 the Bank incurred considerable danger. Had the mob attacked the establishment at the commencement of the riots, the consequences might have proved fatal. Luckily, however, they delayed their attack till time had been afforded for providing a force sufficient to insure its safety. Since that period a considerable military force is nightly placed in the interior of the Bank, as a protection in any emergency that may occur.

spension cash- yments 1797.

The year 1797 is the most important epoch in the recent history of the Bank. Owing partly to events connected with the war in which we were then engaged; to loans to the Emperor of Germany; to bills drawn on the treasury at home by the British agents abroad; and partly, and chiefly, perhaps, to the advances most unwillingly made by the Bank to government, which prevented the directors from having a sufficient control over their issues, the exchanges became unfavourable in 1795, and in that and the following year large sums of specie were drawn from the Bank. In the latter end of 1796 and beginning of 1797, considerable apprehensions were entertained of invasion, and rumours were propagated of descents having been actually made on the coast. In consequence of the fears that were thus excited, runs were made on the provincial banks in different parts of the country; and some of them having failed, the panic became general, and extended itself to London. Demands for cash poured in upon the Bank from all quarters; and, on Saturday the 25th of February 1797, she had only L.1,272,000 of cash and bullion in her coffers, with every prospect of a violent run taking place on the following Monday. In this emergency, an order in council was issued on Sunday the 26th, prohibiting the directors from paying their notes in cash until the sense of parliament should be taken on the subject. And after parliament met, and the measure had been much discussed, it was agreed to continue the restriction till six months after the signature of a definitive treaty of peace.

As soon as the order in council prohibiting payments in cash appeared, a meeting of the principal bankers, merchants, traders, &c. of the metropolis, was held at the Mansion-house when a resolution was agreed to, and very numerously signed, pledging, as had been done in 1745, those present to accept, and to use every means in their power to cause bank-notes to be accepted, as cash in all transactions. This resolution tended to allay the apprehensions that the restriction had excited.

Parliament being sitting at the time, a committee was immediately appointed to examine into the affairs of the Bank; and their report put to rest whatever doubts might have been entertained with respect to the solvency of the establishment, by showing, that at the moment when the order in council apeared, the Bank was possessed of property to the amount of L.15,513,690, after all claims upon her had been deducted.

Much difference of opinion has existed with respect to the policy of the restriction in 1797; but, considering the peculiar circumstances under which it took place, its expediency seems abundantly obvious. The run did not originate in any over-issue of bank-paper, but grew entirely out of political causes. As long as the alarms of invasion continued, it was clear that no bank-paper immediately convertible into gold would remain in circulation. And as the Bank, although possessed of ample funds, was without the means of instantly retiring her notes, she might, but for the interference of government, have been obliged to stop payment; an event which, had it occurred, must have produced consequences in the last degree fatal to the public interests.

Resumption of cash-payments in 1821.

The error of the government did not consist in their coming to the assistance of the Bank, but in their continuing the restriction after the alarm of invasion had ceased, and there was nothing to hinder the Bank from safely reverting to specie payments. We have already pointed out (see article Money, vol. xv. p. 402) the influence of the suspension upon the conduct of the Bank, and the depreciation to which it led. But the destruction of country-bank paper in 1814, 1815, and 1816, having, by reducing the amount of currency, raised its value nearly to a level with that of gold, the legislature was able to revert with comparatively little difficulty to the old standard. The act for this purpose, 59 Geo. III. cap. 78, has been commonly called Peel's bill, from its having been introduced and carried through parliament by Mr (now Sir Robert) Peel. To facilitate the return to specie payments, the Bank was authorized, in the first instance, to pay in bars of standard bullion. She, however, recommenced payments in coin in May 1821, and has since continued them without interruption.

Bank-notes made legal tender everywhere except at the Bank.

Having already given some account of the derangements of the currency in 1825–26, and in 1836–37, it is needless again to allude to them here. When the charter was renewed in 1833, the notes of the Bank of England were made legal tender everywhere except at the Bank. Of the wisdom of this regulation no doubt can be entertained. Bank-notes are necessarily always equivalent to bullion; and by making them substitutes for coin at country banks, the demand for the latter during periods of alarm or runs is materially diminished, and the stability of the Bank and of the pecuniary system of the country proportionally increased. Since 1826 the Bank has established branches in some of the great commercial towns.

Principle on which the Bank endeavours to regulate her conduct.

The principle which the Bank endeavours to keep in view in conducting her business is, that she should so manage her affairs as to have always on hand a stock of coin and bullion equal to a third part of her liabilities; that is, to a third part of the gross amount of her issues and deposits. But in practice she is obliged frequently to depart from this rule; and we have already seen that the circumstances under which the Bank is placed, in consequence of there being hundreds of rival issuers, are such as to make it impossible for her to abide constantly by any system in the regulation of her issues, or to act in the way that it would be for her interest as well as her duty to act were she the sole issuer of paper.

Bank of England in connection with the government.

The Bank of England transacts the whole business of government. "She acts not only," says Dr Smith, "as an ordinary bank, but as a great engine of state. She receives and pays the greater part of the annuities which are due to the creditors of the public; she circulates exchequer bills; and she advances to the government the annual amount of the land and malt taxes, which are frequently not paid till some years thereafter." Previously to 1834 the Bank received about L.270,000 a year from the public for her trouble in managing the national debt, paying dividends, transferring stock, &c. But the act renewing the charter having directed that L.120,000 should be deducted from this charge, it now amounts to about L.150,000 a year.

Assistance rendered by Bank to the mercantile interest.

The greater part of the paper of the Bank has generally been issued in the way of advances or loans to government, upon security of certain branches of the revenue, and in the purchase of exchequer bills and other government securities, and bullion. But her issues through the medium of discounts and loans to individuals have notwithstanding been at all times considerable, while during periods of distress they are often very large. Generally speaking, however, the directors do not think it advisable to enter into competition with private bankers in the transacting of ordinary banking business, or in the discounting of ordinary mercantile paper; and for this reason the interest charged by them is usually one or one and a half per cent. higher than that charged by private bankers and dealers in discounts. When, however, any circumstances occur to occasion a pressure in the money market, the market rate of interest immediately rises to the rate fixed by the Bank, and on such occasions the private bankers and the public generally resort to her for aid. She then becomes as it were a *point d'appui*—a bank of support—and has frequently rendered in that capacity essential service, as in the famous instances of 1792–93, 1815–16, 1825–26, and 1836–37. The interference of the Bank on the latter occasion, in propping up the Northern and Central Bank, though in some respects objectionable, and in supporting the American houses till they got their engagements greatly reduced, no doubt averted a severe pecuniary crisis.

The Bank of England allows no interest, either at the head office in London, or at the branches, for deposits. She is, we believe, influenced in this respect by an apprehension, that were she to allow interest, she might be encumbered with too great an accumulation of deposits, which it might be difficult to employ advantageously, and which, in a period of alarm, might endanger her security. It is not to be denied that there is great weight in these considerations.

The dividends on bank stock, from 1767 to the present time, have been:—From 1767 to 1781, five and a half per cent. per annum; from 1781 to 1788, six per cent.; from 1788 to 1807, seven per cent.; from 1807 to 1823, ten per cent.; and from 1823 to the present time (1838) eight per cent. The sums paid as dividends are exclusive of those which have occasionally been advanced as bonuses: the latter amount, since 1799, to L.3,783,780, over and above the increase of the Bank's capital in 1816, which amounted to L.2,910,600.

N. B.—The rest is found by adding together the circulation and deposits, and deducting their amount from the amount of the securities and bullion.

Joint-stock banks of England and Wales. How constituted.

It will be unnecessary, after the principles laid down and the details given in the previous parts of this article, to enter at any considerable length into an examination of the constitution of the joint-stock banks which combine with the business of deposit banks that of banks for the issue of paper. They consist of bodies of partners, varying from seven to nearly 1500, each holding one or more shares of the company's stock, and they are uniformly managed by boards of directors appointed by, and generally responsible to, the body of shareholders. The conditions of copartnery vary materially in different associations; but the above are distinguishing features common to them all. There can be no doubt that several of these banks are discreetly managed, possess adequate capital, and afford the amplest security to their customers and the public. But it is very doubtful whether this can be truly said of the greater number of these establishments. The shares in many joint-stock banks are very small, few being above L.100, the greater number not exceeding L.50, whilst many are only L.25, and some not more than L.10, and even L.5! Generally, too, it is understood, or rather it is distinctly set forth in the prospectus, that not more than five, ten, or twenty per cent. of these shares is to be called for, so that an individual who has ten or twenty shillings to spare may become a shareholder in a bank. And, owing to a practice, or rather a flagrant abuse, introduced into the management of various banks, by which they make large advances or discounts on the credit of the stock held by the shareholders, not a few individuals in doubtful, [or even desperate circumstances, take shares in them, in the view of obtaining loans, and bolstering up their credit! The great danger arising from such banks is obvious; and were one of them to stop payment, it is plain, even though the claims on it should be ultimately made good, that they could be so only at the cost, and perhaps ruin, of such of its proprietors as had abstained from the abusive practices resorted to by others. It may well, indeed, excite astonishment, that any one who can really afford to make a *bona fide* purchase of shares in a bank should be foolhardy enough to embark in such concerns.

A knowledge of the circumstances now stated, and of the sort of agency by which certain joint-stock banks have been established and conducted,[1] having been generally diffused, a secret committee was appointed by the House of Commons in 1836, to inquire into the operation of the act 7 Geo. IV. cap. 46, permitting the establishment of joint-stock banks; and whether it was expedient to make any alteration in its provisions. The report of this committee, and of a second committee appointed in 1837, with portions of the evidence taken before them, have since been published, and confirm all the conclusions of those who had contended that the existing system required material amendment. The committee of 1836 stated that,—

atements the mmittee 1836.

"Subject to the local restrictions imposed for the protection of the privilege of the Bank of England, it is open to any number of persons to form a company for joint-stock banking, whether for the purpose of deposit, or of issue, or of both.

"1. The law imposes on the joint-stock banks no preliminary obligation beyond the payment of a license duty, and the registration of the names of shareholders at the stamp-office.

"2. The law does not require that the deed of settlement shall be considered or revised by any competent authority whatever; and no precaution is taken to enforce the insertion in such deeds, of clauses the most obvious and necessary.

"3. The law does not impose any restrictions upon the amount of nominal capital. This will be found to vary from L.5,000,000 to L.100,000; and in one instance an unlimited power is reserved for issuing shares to any extent.

"4. The law does not impose any obligation that the whole or any certain amount of shares shall be subscribed for before banking operations commence. In many instances banks commence their business before one half of the shares are subscribed for, and 10,000, 20,000, and 30,000 shares are reserved to be issued at the discretion of the directors.

"5. The law does not enforce any rule with respect to the nominal amount of shares. These will be found to vary from L.1000 to L.5. The effects of this variation are strongly stated in the evidence.

"6. The law does not enforce any rule with respect to the amount of capital paid up before the commencement of business. This will be found to vary from L.105 to L.5.

"7. The law does not provide for any publication of the liabilities and assets of these banks, nor does it enforce the communication of any balance-sheet to the proprietors at large.

"8. The law does not impose any restrictions by which care shall be taken that dividends are paid out of banking profits only, and that bad or doubtful debts are first written off.

"9. The law does not prohibit purchases, sales, and speculative traffic on the part of these companies in their own stock, nor advances to be made on the credit of their own shares.

"10. The law does not provide that the guarantee fund shall be kept apart and invested in government or other securities.

"11. The law does not limit the number of branches, or the distance of such branches from the central bank.

"12. The law is not sufficiently stringent to insure to the public that the names registered at the stamp-office are the names of persons *bona fide* proprietors, who have signed the deed of settlement, and who are responsible to the public.

"13. The provisions of the law appear inadequate, or at least are disregarded, so far as they impose upon banks the obligation of making their notes payable at the places of issue.

"All these separate questions appear to your committee deserving of the most serious consideration, with a view to the future stability of the banks throughout the united kingdom, the maintenance of commercial credit, and the preservation of the currency in a sound state."

Remedial measures that should be adopted.

We do not, however, think that it would be at all necessary, in providing for a secure system of joint-stock banking, to make any regulations with respect to many of the points noticed by the committee, as to which the law is silent. At present every partner in a joint-stock bank is liable to the public for the whole debts of the firm; and this may be truly said to be the saving principle of the system, and without which it would be an unmixed intolerable evil. No individual should, however, by merely withdrawing from a joint-stock concern, get rid of his liabilities in connection with it. To prevent fraud, and to insure due caution, these ought to continue for a period of three years at least after he has publicly withdrawn his name. The public, too, are clearly entitled to know the partners in joint-stock associations, that is, to be informed who the individuals are with whom they are dealing, and who are responsible to them. But, unluckily, no effective means are taken for supplying the public with this necessary information, and, consequently, of properly discriminating between one establishment and another. The act of 1833 (3 and 4 Will. IV. c. 83) directed, as previously stated, that an account of the places where they carry on business, and of the names and residences of the partners, should be quarterly transmitted to the stamp-office. But doubts have been entertained as to the correctness of these returns, and comparatively little use has been, or indeed can be, made of them. The accounts of the names and residences of the proprietors are not published; but are carefully secluded from the public eye, in the repositories of Somerset House! It is true that these lists may be seen by those who choose to apply at the office, for a small fee, and that certified copies may be procured at no great expense. But few know that such returns exist, and still fewer have the opportunity or think of availing themselves of them as sources of information. To render them of any real utility, they should be brought under the public eye, by being hung up in the offices of the banks to which they refer, and periodically published in the newspapers of the places where they carry on business. By this means the public would know exactly to whom they had to look, and would act accordingly. They would not be deceived, as they are liable to be at present, by supposing that, because a bank has a number of partners, some of them must be opulent and trustworthy. They would know the precise state of the fact; and if it were seen from the quarterly returns, that opulent and intelligent individuals were withdrawing from any bank, every one would be put on his guard, and would naturally conclude that the parties had very sufficient reasons for quitting the concern. Thus far publicity may be made effectual, and would be of the very greatest importance. Neither is it possible to allege a single plausible objection to this proposal. It interferes in no degree, nor in any way, with the proceedings of the parties; all that it does is to declare who and what they are, and to this degree of publicity no honest man will object. But we have great doubts whether it be possible to carry publicity farther than this. The committee state that "the law does not provide for any publication of the liabilities and assets of these banks, nor does it enforce the publication of any balance-sheet to the proprietors at large;" and it has been proposed to compel the periodical publication of a statement of this sort. But it is very questionable whether any such publication would not be a great deal worse than useless. It is not proposed that commissioners should be appointed to inspect the accounts of the different banks, and to see that the returns are accurate. This would be too inquisitorial, too cumbrous, and too costly a plan to be thought of for a moment. There would be nothing for it, in fact, but to trust entirely to the honour of the parties. Hence, in all cases in which a disclosure would be really useful, the publication of an account of assets and liabilities would afford the means of deceiving the public, and of representing a bankrupt concern as being in a prosperous condition. Supposing, however, that the parties were in all instances perfectly honest, still the publication of a balance-sheet would be good for nothing. Every one knows how sanguine people are in relation to their own affairs; and that debts and obligations which other parties would hardly reckon worth any thing, are estimated by them as if they were so much bullion. But, independently of this, the futility of the thing is obvious. A bank with a capital of L.100,000 discounts bills and other obligations to the extent, perhaps, of L.300,000 or L.400,000; the fact that it has discounted them shows that it believes these bills and obligations to be good; and they will, consequently, be reckoned amongst its assets. But should a revulsion take place, or any circumstance occur to shake credit, these bills may not be worth L.100,000; and those who have dealt with the bank, on the hypothesis of its having capital and assets more than enough to meet all its obligations, will find to their cost that it is not possessed of a single shilling, but is, on the contrary, some L.200,000 or L.300,000 worse than nothing!

---

[1] See Edinburgh Review, No. 128, art. 6; and the accounts of the Norwich Bank, and of the Northern and Central Bank, in the Reports of the Committees of 1836 and 1837.

The committee seem to think that some regulation should be enacted, providing that a certain portion of its capital should be paid up before a bank begins business. But we incline to think that the better way would be to prohibit all advertising of *nominal* capitals; and to enact that the capital actually *paid up*, whatever its amount, shall always be represented as, and held to be, the capital of the bank. But although such a regulation were made, there would be no security that the capital said to have been paid up had really been paid into the coffers of the bank, or that, if received, it had not again been lent out, in one way or other, to the partners. Perhaps it might be good policy to enact that no shares should be issued under a certain sum, as L.50; and that no loans should be made to the partners on the credit of their stock. But we should not be inclined to lay much stress on the former regulation; and the latter might, and no doubt would, be defeated in a thousand ways.

We are decidedly hostile to a proposal we have heard made, and which seems to be countenanced by the committee, for obliging all banks to establish a guarantee fund; that is, for obliging them to accumulate a portion of their profits as a reserve stock. But where is the security that such reserve would be always deducted from the profits? The truth is, that bankrupt and fraudulent concerns, and none else, would gain by such a regulation; inasmuch as it would enable them, by appearing to be prosperous, the better to deceive the public, and to blind them as to the real state of their affairs. It is plainly worse than absurd to teach the public to depend on guarantees that cannot be enforced, and which consequently must be good for nothing, unless it be to tempt to and conceal fraud. The knowledge of who the partners are in a bank, and their unlimited responsibility, are the only securities that, speaking generally, are worth anything. If these cannot protect the public from fraud and loss, nothing else will; and the question will come to be, not whether the system should be reformed, but whether it should be entirely abolished.

We have already noticed the extraordinary multiplication of branch-banks all over the country; and it is not very difficult to discover why banks of issue, at least, are so very anxious about the establishment of these outworks. They are bound, it seems, by the present law, to pay their notes only at the parent establishment; so that, by issuing them at a branch bank, perhaps a hundred miles distant from the head bank, the chances are ten to one that they will continue for a much longer period in circulation, and that they will consequently be able to carry on business with a much less amount of capital, than if they were, as they ought to be, obliged to pay their notes at the branches as well as at the principal office. It is obvious, indeed, that the convertibility of the paper, even of first-class banks, into either cash or Bank of England notes, is at present exceedingly imperfect; and that very great facilities are afforded for getting the worst class of notes into circulation, and for keeping them afloat, even after their quality may be suspected. This defect in the law ought undoubtedly to be amended, by obliging all banks that issue notes to pay them indifferently at any of their offices. But we incline to think that parliament might go farther than this, and that it should enact that no branch be established, whether for the issue of notes or otherwise, beyond a certain distance (say fifty miles) from the head office.

Several of the points recapitulated by the committee, as to which the law is silent, respect the rights and interests of the partners in joint-stock banks, in relation to each other, and not as between them and the public. But it is always a very difficult matter to interfere to dictate the footing on which parties in any undertaking should stand amongst themselves. Much should, in such cases, be left to the judgment of the parties; and public regulations, if enforced at all, should only go to prevent obvious and acknowledged abuse. The parties may in most cases be safely left to take care of themselves. The protection of the public interest is the paramount consideration; and we do not well know what can be done to effect this, in the case at least of such banks as do not issue notes, other than the making known who their partners are.

The committee, like the manager who overlooked the part of the prince in casting the play of Hamlet, have omitted all reference to by far the most important matter connected with their inquiry,—the suppression of the issues of private and joint-stock banks. Though the regulations proposed or hinted at by the committee were adopted, and were as effectual as they are sure to be ineffectual and mischievous, they would do nothing to prevent those oscillations in the amount and value of money inherent in a currency supplied by different issuers, and which periodically overspread the country with bankruptcy and ruin. Even the exacting of security for their issues, the only regulation it is possible to adopt in regard to them which can be of any real value, though it would mitigate their violence, would not get rid of these destructive fluctuations. Nothing, as has already been fully shown, can do this short of the suppression of all local issues; and all schemes for the improvement of banking in England which do not proceed on this assumption, savour more of quackery and delusion than of anything else, and deserve but little attention.

TABLES EXHIBITING THE NAMES, PARTNERS, CAPITAL, &C. OF JOINT-STOCK BANKS.

I.—Official Return of all Places where United or Joint-Stock Banks have been established under the Act 7 Geo. IV. c. 46; with the Dates when such Banks were established, and the Number of Partners therein, down to the 22d November 1837. Subjoined is the paid-up Capital and Circulation of certain Banks, according to the Returns rendered to the Secret Committee of 1837.

History and constitution of Scotch banks.

The act of 1708, preventing more than six individuals from entering into a partnership for carrying on the business of banking, did not extend to Scotland. In consequence of this exemption, several banking companies, with numerous bodies of partners, have always existed in that part of the empire. The Bank of Scotland was established by act of parliament in 1695. By the terms of its charter, it enjoyed, for twenty-one years, the exclusive privilege of issuing notes in Scotland. Its original capital was only L.100,000. But it was increased to L.200,000 in 1744, and now amounts to L.1,500,000, of which L.1,000,000 has been paid up.

The Royal Bank of Scotland was established in 1727. Its original capital was L.151,000. At present it amounts to L.2,000,000, which has been all paid up.

The British Linen Company was incorporated in 1746, for the purpose, as its name implies, of undertaking the manufacture of linen. But the views in which it originated were speedily abandoned, and it became a banking company only. Its paid up capital amounts to L.500,000.

Exclusively of the above, there are two other chartered banks in Scotland; the Commercial Bank, established in 1810, and the National Bank of Scotland, established in 1825. The former has a paid-up capital of L.600,000, and the latter of L.500,000.

None of the other banking companies established in Scotland are chartered associations; and the partners are jointly and individually liable to the whole extent of their fortunes for the debts of the firms. Some of them, as the Aberdeen Town and County Bank, the Dundee Commercial Bank, the Perth Banking Company, &c. have very numerous bodies of partners. Generally speaking, they have been eminently successful. An original share, L.150, of the stock of the Aberdeen Banking Company, established in 1767, is now (1838) worth no less that L.2500! Their affairs are uniformly conducted by a board of directors chosen by the shareholders.

There are very few banks with less than six partners in Scotland. Almost all the great joint-stock banks have numerous branches, so that there is hardly a town or village of any consequence without two or more banks.

The Bank of Scotland began to issue one-pound notes as early as 1704, and their issue has since been continued without interruption. With only one exception, all the Scotch banks issue notes; and, taking their aggregate circulation at from L.3,500,000 to L.4,000,000, it is supposed that from L.2,000,000 to L.2,500,000 consists of notes for L.1. In 1826 it was proposed to suppress one-pound notes in Scotland as well as in England; but the measure having been strongly objected to by the people of Scotland, as being at once oppressive and unnecessary, was abandoned.

easons r the few ilures nong otch nks.

There have been very few bankruptcies amongst the Scotch banks. This superior stability is to be ascribed to a variety of causes; partly to the great wealth of the early established banks, which had a considerable influence in preventing an inferior class of banks acquiring any hold on the public confidence; partly to the comparatively little risk attending the business of banking in Scotland; partly to the facilities afforded by the Scotch law for attaching a debtor's property, whether it consist of land or moveables; and partly and principally, perhaps, to the fact of the Scotch banks being but indirectly and slightly affected by a depression of the exchange and an efflux of bullion.

ppres- n of lo- notes Scotland neces- y.

The circumstances now mentioned render it unnecessary to enforce that suppression of local issues in Scotland which is so indispensable in England, where the system of provincial banking is of a very inferior description, the risk attending the business much greater, and where any excess in the amount of the currency necessarily occasions a fall of the exchange and a demand for bullion. The commerce and population of Scotland are too limited, and that country is too remote from the metropolis, or from the centre of the monied world, the pivot on which the exchanges turn, to make it of importance that her currency should be identical with that of England. We believe that the Scotch attach much more importance than it deserves to the issue of paper, and especially to the issue of one-pound notes; still, however, we do not think that the circumstances are at present such as to call for or warrant any attempt to introduce any material changes in their banking system.

posits.

All the Scotch banks receive deposits, even of the low amount of L.10, and allow interest on them at from one to two per cent. below the market rate. But should a deposit be unusually large, as from L.5000 to L.10,000, a special agreement is usually made with regard to it. This part of the system has been particularly advantageous. It, in fact, renders the Scotch banks a sort of savings' banks for all classes; and their readily receiving all sorts of deposits at a reasonable rate of interest, has tended to diffuse a spirit of economy and parsimony among the people that would not otherwise have existed. The total deposits in the hands of the Scotch banks are believed at present (1838) to exceed L.25,000,000, of which fully a half is understood to be in sums of from L.10 to L.200.

Cash-accounts.

The Scotch banks make advances in the way of discounts and loans, and on what are called cash-credits or cash-accounts. By the latter are meant credits given by the banks for specified sums to individuals, each of whom gives a bond for the sum in his account, with two or more individuals as sureties for its payment. Persons having such accounts draw upon them for whatever sums within their amount they have occasion for, repaying these advances as they find opportunity, but generally within short periods. Interest is charged only on the average balance which may be found due to the bank. The total number of these accounts in Scotland in 1826 was estimated at about 12,000; and it may now, perhaps, be taken at about 14,000. They are believed to average about L.500; few are for less than L.100, and fewer still above L.5000.

It has been contended, and by no less an authority than Adam Smith, that this species of accommodation gives the Scotch merchants and traders a double command of capital. "They may discount their bills of exchange," says he, "as easily as the English merchants, and have, besides, the additional conveniency of their cash-accounts."[1] But this is an obvious error. The circulation will take off only a certain quantity of paper; and to whatever extent it may be issued by means of cash-accounts, so much the less can be issued in the way of discounts. The advantage of a cash-account does not really consist in its enabling a banker to enlarge his advances to his customers, but in the extreme facility it affords of making them. An individual who has obtained such an account may operate upon it at any time he pleases, and by drafts for any amount; an advantage he could not enjoy to any thing like the same extent, without an infinite deal of trouble and expense, were the loans or advances made to him through the discounting of bills.

The Scotch banks draw upon London at twenty days' date. This is denominated the par of exchange between London and Edinburgh.

The following table, extracted from a very useful publication,[2] exhibits the partners, branches, capital, prices of shares, dividends, &c. in the five chartered banks, in December 1837; and it also shows the aggregate partners, branches, capital, &c. of the other joint-stock banks then existing in Scotland.

	Partners.	Branches.	Paid up Capital.	Dividend.			Shares Paid.			Present Price.

[2] Oliver and Boyd's Almanack for 1838.

System of banking in Ireland.

"In no country, perhaps," says Sir Henry Parnell, "has the issuing of paper-money been carried to such an injurious excess as in Ireland. A national bank was established in 1783, with similar privileges to those of the Bank of England, in respect to the restriction of more than six partners in a bank; and the injury that Ireland has sustained from the repeated failure of banks may be mainly attributed to this defective regulation. Had the trade of banking been left as free in Ireland as it is in Scotland, the want of paper-money that would have arisen with the progress of trade, would in all probability have been supplied by joint-stock companies supported with large capitals, and governed by wise and effectual rules.

"In 1797, when the Bank of England suspended its payments, the same privilege was extended to Ireland; and after this period the issues of the Bank of Ireland were rapidly increased. In 1797, the amount of the notes of the Bank of Ireland in circulation was L.621,917; in 1810, L.2,266,471; and in 1814, L.2,986,999.

"These increased issues led to corresponding increased issues by the private banks, of which the number was fifty in the year 1804. The consequence of this increase of paper was its great depreciation; the price of bullion and guineas arose to ten per cent. above the mint price; and the exchange with London became as high as eighteen per cent., the par being 8$\frac{1}{3}$. This unfavourable exchange was afterwards corrected, not by any reduction in the issues of the Bank of Ireland, but by the depreciation of the British currency in the year 1810, when the exchange between London and Dublin settled again at about par. (See article EXCHANGE.)

"The loss that Ireland has sustained by the failure of banks may be described in a few words. It appears, by the Report of the Committee on Irish Exchanges in 1804, that there were at that time in Ireland fifty registered banks. Since that year a great many more have been established, but the whole have failed, one after the other, involving the country from time to time in immense distress, with the following exceptions:—*First*, a few that withdrew from business; *secondly*, four banks in Dublin; *thirdly*, three at Belfast; and, *lastly*, one at Mallow. These eight banks, with the new Provincial Bank and the Bank of Ireland, are the only banks now (1827) existing in Ireland.

"In 1821, in consequence of eleven banks having failed nearly at the same time, in the preceding year, in the south of Ireland, government succeeded in making an arrangement with the Bank of Ireland, by which joint-stock companies were allowed to be established at a distance of fifty miles (Irish) from Dublin, and the bank was permitted to increase its capital L.500,000. The act 1 and 2 Geo. IV. c. 72, was founded on this agreement. But ministers having omitted to repeal in this act various restrictions on the trade of banking that had been imposed by 33 Geo. II. c. 14, no new company was formed. In 1824 a party of merchants of Belfast, wishing to establish a joint-stock company, petitioned parliament for the repeal of this act of Geo. II.; and an act was accordingly passed in that session, repealing some of its most objectionable restrictions. (5 Geo. IV. c. 73.)

"In consequence of this act, the Northern Bank of Belfast was converted into a joint-stock company, with a capital of L.500,000, and commenced business on the 1st of January 1825. But the restrictions of 33 Geo. II., and certain provisions contained in the acts 1 and 2 Geo. III., and 5 Geo. IV., obstructed the progress of this company, and they found it necessary to apply to government to remove them; and a bill was accordingly introduced, which would have repealed all the obnoxious clauses of the 33d Geo. II., had it not been so altered in the committee as to leave several of them in force. In 1825 the Provincial Bank of Ireland commenced business with a capital of L.2,000,000; and the Bank of Ireland has of late established branches in all the principal towns.

"The losses that have been sustained in Ireland by abusing the power of issuing paper have been so great, that much more is necessary to be done by way of protecting the public from future loss, than the measure proposed last session (1826) by ministers, of abolishing small notes, and the measure already adopted, of allowing joint-stock companies to be established in the interior of the country. As the main source of the evil consists in the interference of the law in creating a national bank with exclusive privileges, the first step that ought to be taken for introducing a good system into Ireland, is the getting rid of such a bank, and opening the trade of banking in Dublin. The next measure should be the requiring of each bank to give security for the amount of paper that is issued; for after the experience of the ignorance with which the Irish banks have conducted their business, and the derangement of the natural course of the trade, by the long existence of the Bank of Ireland, it would be unwise to calculate upon a sound system of banking speedily supplanting that which has been established.

"Under the circumstances in which Ireland is placed, nothing would so much contribute to her rapid improvement in wealth, as the introducing of the Scotch plan of cash credits, and of paying interest on deposits. By cash credits, the capital which now exists would be rendered more efficient, and the paying of interest on small deposits, would lead to habits of economy, and to the more rapid accumulation of new capital.

"The charter of the Bank of Ireland has still to run till the year 1838."[1]

Since Sir Henry Parnell published the valuable pamphlet from which we have taken the foregoing extract, several joint-stock banking companies have been founded in Ireland. The Provincial Bank, to which Sir Henry alludes, has a paid up-capital of L.500,000, and has been well and profitably managed. But others have been less fortunate. The Agricultural and Commercial Bank of Ireland, established in 1834, with 2170 partners, a paid-up capital of L.352,790, and many branches, stopped payment during the pressure in November 1836, and by doing so involved many persons in great distress. It would appear, from the statement of the auditors appointed to audit the accounts, &c. of this bank, given in the Appendix to the Commons' Report of 1837, that it had, to say the least, been very ill managed. "We have found," say the auditors, "that there was no efficient control over the branches, and that the system of inspection was most imperfect. A complete absence of plan for checking the accounts existed at the head office in Dublin; and *the book-keeping has been so faulty, that we are convinced no accurate balance-sheet could at any time have been constructed*. We have looked in vain for an account of 'outfit,' or of 'premiums' received; and we must add, that the personal accounts at the head office require a diligent and searching revision."

More than half of the existing Irish joint-stock banks, amounting to eighteen, were established in 1836 and 1837. It is to be hoped that these establishments will take warning by the disasters in which the Agricultural Bank has been involved, and adopt a safer course. But if the power to issue paper-money be continued to these establishments, it is clear that no time should be lost in compelling them to give security for its payment. Unless this measure be inforced, or the issues be entirely suppressed, we run little risk in affirming that Ireland has not seen either the last or most severe of those violent oscillations in the amount and value of money which produce so much bankruptcy and ruin.

---

[1] Observations on Paper-Money, &c. by Sir Henry Parnell, pp. 171–177.

The capital of the Bank of Ireland amounts to L.2,769,230. The rate of dividend from 1830 to 1836 was nine per cent.; in 1836 it was eight and a half per cent. The charter, which expires in the course of the present year, has not as yet been renewed. It is almost needless to add, that there is no room or ground whatever for the continuance of the exclusive privilege the Bank of Ireland has hitherto enjoyed. We subjoin an

Account showing the Circulation of the Bank of Ireland from 1823 *to* 1836, *both inclusive.*

Years.	Large Notes.	Small Notes.	Post Bills.	Total Average Circulation.

ks.

It would far exceed our limits to enter into any detailed statements with respect to the banks and banking systems of foreign countries; we shall therefore confine ourselves to a brief notice of such banks as have been most celebrated, or are at present of the greatest importance.

nk of
nice.

The Bank of Venice was the most ancient bank in Europe. Neither its date nor the circumstances which led to its establishment are exactly known. Historians inform us, that in 1171, the republic being hard pressed for money, levied a forced contribution on the richest citizens, giving them in return a perpetual annuity at the rate of four per cent. An office was established for the payment of this interest, which, in the sequel, became the Bank of Venice. This might be effected as follows: The interest on the loan to government being paid punctually, every claim registered in the books of the office would be considered as a productive capital; and these claims, or the right of receiving the annuity accruing thereon, must soon have been transferred, by demise or cession, from one person to another. This practice would naturally suggest to holders of stock the simple and easy method of discharging their mutual debts by transfers on the office books, and as soon as they became sensible of the advantages to be derived from this method of accounting, bank-money was invented.

The Bank of Venice was essentially a deposit bank. Though established without a capital, its bills bore at all times an agio or premium above the current money of the republic. The invasion of the French in 1797 occasioned the ruin of this establishment.

B k of
A ster-
da.

The Bank of Amsterdam was founded in 1609, on strictly commercial principles and views, and not to afford any assistance, or to commix with the finances of the state. Amsterdam was then the great entrepôt of the commerce of the world, and of course the coins of all Europe passed current in it. Many of them, however, were so worn and defaced as to reduce their general average value to about nine per cent. less than their mint value; and, in consequence, the new coins were immediately melted down and exported. The currency of the city was thus exposed to great fluctuations; and it was chiefly to remedy this inconvenience, and to fix the value or par of the current money of the country, that the merchants of Amsterdam established a "bank," on the model of that of Venice. Its first capital was formed of Spanish ducats or ducatoons, a silver coin which Spain had struck in the war with Holland, and with which the tide of commerce had enriched the country it was formed to overthrow! The bank afterwards accepted the coins of all countries, worn or new, at their intrinsic value, and made its own bank-money payable in standard coin of the country, of full weight, deducting a "brassage" for the expense of coinage, and giving a credit on its books, or "bank-money," for the deposits.

The Bank of Amsterdam professed not to lend out any part of the specie deposited with it, but to keep in its coffers all that was inscribed on its books. In 1672, when Louis XIV. penetrated to Utrecht, almost every one who had an account with the bank demanded his deposit, and these were paid off so readily, that no suspicion could exist as to the fidelity of the administration. Many of the coins then brought forth bore marks of the conflagration which happened at the Hôtel de Ville, soon after the establishment of the bank. This good faith was maintained till about the middle of last century, when the managers secretly lent part of their bullion to the East India Company and government. The usual "oaths of office" were taken by a religious magistracy, or rather by the magistracy of a religious people, that all was safe; and the good people of Holland believed, as an article of their creed, that every florin which circulated as bank-money, had its metallic constituent in the treasury of the bank, sealed up and secured by oaths, honesty, and good policy. This blind confidence was dissipated in December 1790, by a declaration that the bank would retain ten per cent. of all deposits, and would return none of a less amount than 2500 florins.

Even this was submitted to and forgiven. But, four years afterwards, on the invasion of the French, the bank was obliged to declare that it had advanced to the states of Holland and West Friesland, and the East India Company, more than 10,500,000 florins, which sum they were unable to make up to their depositors, to whom, however, they assigned their claims on the states and the company. Bank-money, which previously bore an agio of five per cent., immediately fell to sixteen per cent. below current money.

This epoch marked the fall of an institution which had long enjoyed an unlimited credit, and had rendered the greatest services. The amount of the treasure in the vaults of the bank, in 1755, was estimated by Mr Hope at 33,000,000 of florins.[1]

Bank of
Hamburg.

The Bank of Hamburg was established in 1619, on the model of that of Amsterdam. It is a deposit bank, and its affairs are managed according to a system that insures the fullest publicity. It receives no deposits in coin, but only in bullion of a certain degree of fineness. It charges itself with the bullion at the rate of 442 schillings the mark, and issues it at the rate of 444 schillings, being a charge of four ninths, or nearly one half per cent., for its retention. It advances money on jewels to three fourths of their value. The city is answerable for all pledges deposited with the bank: they may be sold by auction if they remain one year and six weeks without any interest being paid. If the value be not claimed within three years, it is forfeited to the poor. This bank is universally admitted to be one of the best managed in Europe.

---

Banks.

Bank of France.

The Bank of France was founded in 1803. The exclusive privilege of issuing notes payable to bearer was granted to it for forty years. The capital of the bank consisted at first of 45,000,000 francs, but it was subsequently increased to 90,000,000 francs, divided into 90,000 shares or *actions* of 1000 francs each. Of these shares, 67,900 are in the hands of the public; 22,100, being purchased up by the bank, form part of her capital. The notes issued by the bank are for 1000 and 500 francs. The dividend varies from six to ten and a half per cent., the latter being its amount in 1837; and there is, besides, a *reserve* retained from the profits, which is vested in the five per cents. A bonus of 200 francs a share was paid out of this reserve to the shareholders in 1820. No bills are discounted that have more than three months to run. The customary rate of discount is four per cent., but it varies according to circumstances. The discounts in 1834 amounted to 306,603,000 francs, but they vary materially from year to year, and are sometimes more than double this amount. The bank is obliged to open a *compte courant* for every one who requires it; and performs services for those who have such accounts, similar to those rendered by the private banks of London to their customers. She is not allowed to charge any commission upon current accounts, so that her only remuneration arises out of the use of the money placed in her hands by the individuals whose payments she makes. This branch of the business is said not to be profitable. There are about 1600 accounts current at the bank; and of the entire expenses of the establishment, amounting to about 900,000 francs a year, *two thirds* are said to be incurred in this department. The bank advances money on pledges of different kinds, such as foreign coin or bullion, government or other securities, &c. It also undertakes the care of valuable articles, as plate, jewels, bills, title-deeds, &c. The charge is one eighth per cent. of the value of each deposit for every period of six months or under. The average circulation of bank notes in 1834 was 207,321,000 francs, the price of a share of the bank's stock on the 8th of January 1838 was 2555 francs, a proof that its condition is believed to be eminently flourishing.

The administration of the bank is vested in a council general of twenty members, viz. seventeen regents, and three censors, who are nominated by two hundred of the principal proprietors. The king appoints the governor and deputy governor. The first must be possessed of a hundred and fifty, and the latter of fifty shares. A *compte rendu* is annually published, and a report by the censors, which together give a very full exposition of the affairs of the bank. The institution is flourishing, and enjoys unlimited credit. (For further details with respect to the Bank of France, see Storch, *Cours d'Economie Politique*, Paris, 1823, tom. iv. pp. 168–180; and the *Comptes Rendus* of the different years.)

For further information as to continental banks and paper-money, the reader is referred to the interesting chapter on that subject in the fourth volume of the *Cours d'Economie Politique* of M. Storch, and to M'Culloch's *Commercial Dictionary*.

System of banking in the United States.

The system of banking in the United States has recently attracted a great deal of attention in this country. The Bank of the United States was incorporated by Congress in 1816, with a capital of 35,000,000 dollars, for the issue of notes and the transacting of ordinary banking business. Its head office was in Philadelphia, but it had branches that carried on an extensive business in most considerable towns of the Union. The charter was limited to twenty years' duration; and the question, whether it should be renewed, was debated with extraordinary vehemence in all parts of America. The late president, General Jackson, was violently opposed to the reincorporating of the bank, and rejected a bill for that purpose, that had been sanctioned by the other two branches of the legislature. A majority of Congress having come round to the president's views, the charter was allowed to expire. It has since, however, received a new charter from the state of Pennsylvania. But this merely enables it to carry on business in that state; though it may obtain, and has, in fact, already obtained leave from some of the other states to establish branches within their limits. It is, however, no longer a national or government bank; but it is now, as formerly, the first monied institution of the new world, and in this respect, indeed, is second only to the Bank of England.

Banks.

We cannot help thinking, that the American government acted throughout the whole of this affair on the most erroneous views. Banking in America is, if possible, in a still worse condition than in England; and there can hardly be a doubt that the establishment of the Bank of the United States was of signal service to the republic, by affording a currency of undoubted solidity, readily accepted in all parts of the Union, and by its operating as a salutary check on the conduct of other banks. General Jackson, and the party of which he was the head, have, or affect to have, a great horror of paper-money. But it would be practising too much on the patience of our readers were we to endeavour to prove by argument the great utility, not to say necessity, of a paper currency of some sort or other, to all great commercial countries like the United States. To suppose that it should be altogether dispensed with, is as absurd as it would be to suppose that they should dispense with their improved roads and carriages. A wise statesman should not attempt to suppress what is indispensable, but should exert himself to obviate its defects, and to make it as suitable as it can be made to the objects in view. This, however, General Jackson and his party have not done. On the contrary, they declared war against the only unexceptionable bank in the Union, and to injure it gave full scope to the rest. Hence, instead of obviating any one of the gross defects inherent in the existing banking system, the proceedings of General Jackson have aggravated and multiplied them in in no common degree; and it is now infected with every vice that it seems possible can belong to banking.

The American banks are all joint-stock associations. But instead of the partners being liable, as in England, for the whole amount of the debts of the banks, they are in general liable only for the amount of their shares, or for some fixed multiple thereof. It is needless to dwell on the temptation to commit fraud held out by this system, which has not a single countervailing advantage to recommend it. The worthlessness of the plan on which the banks were founded was evinced by the fact, that between 1811 and the 1st of May 1830, no fewer than a hundred and sixty-five banks became altogether bankrupt, many of them paying only an insignificant dividend; and this exclusive of a much greater number that stopped for a while, and afterwards resumed payments. The wide-spread mischief resulting from such a state of things has led to the devising of various complicated schemes for insuring the stability and prudent management of banks; but as they all involve regulations which it is impossible to enforce, they are practically worse than useless. In Massachusetts, for example, it is provided that no bank for the issue of notes can go into operation in any way, until at least half its capital stock be paid in gold and silver into the bank, and be actually existing in its coffers, and seen in them by inspectors appointed for that purpose; and the cashier of every bank is bound to make specific returns once a year of its debts and assets, on being required to do so by the secretary of state. But our readers need hardly be told, that these elaborately contrived regulations are really good for nothing, unless it be to afford an easy mode of cheating and defrauding the public. Instances have occurred of banks having borrowed an amount of dollars equal to half their capital, for *a single day*, and of such dollars having been examined by the inspectors appointed for that purpose, and reported by them, and sworn by a majority of the directors to be the first instalment paid by the stockholders of the bank, and intended to remain in it.[1] We do not of course imagine that such disgraceful instances can be of common occurrence; but what is to be thought of a system which permits a company for the issue of paper-money, founded on such an abominable fraud, to enter on business, with a sort of public attestation of its respectability? The publicity, too, to which the American banks are subject, is injurious rather than otherwise. Those who are so disposed may easily manufacture such returns as they think most suitable to their views; and the more respectable banks endeavour, for a month or two previously to the period when they have to make their returns, to increase the amount of bullion in their coffers, by temporary loans, and all manner of devices. The whole system is, in fact, bottomed on the most vicious principles. But it is unnecessary, after what occurred in 1836 and 1837, to insist further upon the gross and glaring defects of American banking. Perhaps no instance is to be found in the history of commerce, of such a wanton over-issue of paper as took place in the United States in 1835 and 1836. The result is known to every body; the revulsion to which this over-issue necessarily led having, in May 1837, compelled every bank in the Union, without, we believe, a single exception, to stop payments.

Owing to the privilege claimed by the different states, and exercised without interruption from the Revolution downwards, it is, we fear, impossible to effect the suppression of local paper in America, or to establish a paper currency which should at all times vary in amount and value, as if it were metallic. But the states have it in their power to do that which is next best; they may compel all banks which issue notes to give security for their issues. This, though it would not prevent destructive oscillations in the amount and value of the currency, would, at all events, prevent those ruinous and ever-recurring stoppages and bankruptcies of the issuers of paper-money, that render the American banking system one of the severest scourges to which any people was ever subjected. Common sense and experience alike demonstrate the inefficacy of all the regulations enacted by the American legislature to prevent the abuse of banking. It is in vain for them to lay it down that the issues shall never exceed a certain proportion of the capital of the bank, and so forth. Such regulations are all very well, provided the banks choose to respect them; but there are no means whatever of insuring their observance; and their only effect is to make the public look for protection and security to what is altogether impotent and worthless for any good purpose. The suppression of local issues is indispensable in order to make a paper currency what it ought to be. If, however, this be impossible in America, there is nothing left but to take security from the issuers of notes. All schemes for the improvement of banks, by making regulations as to the proportion of their issues, and advances to their bullion, capital, &c. are downright delusion and quackery. (c. c.)

Table showing the Number and Capital of the various Banks existing in the United States at the undermentioned periods.

[1] Gouge's Paper-Money and Banking in the United States, part ii. p. 157.

PAPIER MACHÉ. This is a substance made of cuttings of white or brown paper, boiled in water, and beaten in a mortar, till they are reduced to a kind of paste, and then boiled with a solution of gumarabic or of size, to give tenacity to the paste, which is afterwards formed into different articles, by pressing it into oiled moulds. When dry, the work is done over with a mixture of size and lamp-black, and afterwards varnished. The black varnish for these articles is prepared as follows. Some colophony, or turpentine boiled down till it becomes black and friable, is melted in a glazed earthen vessel, and thrice as much amber in fine powder is sprinkled in by degrees, with the addition now and then of a little spirit or oil of turpentine. When the amber is melted, sprinkle in the same quantity of sarcocolla, continuing to stir them, and to add more spirit of turpentine, until the whole becomes fluid; then strain it out clear through a coarse hair bag, pressing it gently between hot boards. This varnish, mixed with ivory-black in fine powder, is applied, in a hot room, on the dried paper paste, which is then set in a gently heated oven, next day in a hotter oven, and the third day in a very hot one, and allowed to remain each time till the oven grows cold. The paste thus varnished is hard, durable, glossy, and is not affected by liquor, however hot.

PAPHLAGONIA, in *Ancient Geography*, a country of Asia Minor, beginning at Parthenius, a river of Bithynia, on the west, extending in length to the Halys on the east, and having the Euxine on the north, and Galatia on the south.

PAPHOS, in *Ancient Geography*, two adjoining islands on the western side of the island of Cyprus, the one called *Palæa Paphos*, and the other *Nea Paphos*; and when Paphos is mentioned without an adjunct, this latter is always understood.

PAPIAS, bishop of Hierapolis, a city of Phrygia, was the disciple of St John the Evangelist, and the companion of Polycarp. He composed a work in five books, entitled Expositions of the Discourses of our Lord, of which there are only some fragments now remaining. It was Papias who introduced the opinion of the Millenarians.

PAPINIAN, a celebrated Roman lawyer of the third century. The Emperor Severus had so high an opinion of his worth that he recommended his sons Caracalla and Geta to the care of the jurisconsult. Caracalla having murdered his brother, ordered Papinian to compose a discourse excusing this murder to the senate and people; but the lawyer refused to undertake the disgraceful task assigned him, and the brutal emperor, enraged at his refusal, ordered him to be beheaded, and his body dragged through the streets of Rome. Papinian wrote several treatises on professional subjects.

PAPISTS. See POPE and ROMAN CATHOLICS.

PAPPAL, a district of Borneo, on the north-east coast, the limits of which, on the north, are Sampanmangio and Keemanees river, in latitude 5. 30. north. The productions of this coast are, in general, sago, rice, betel-nut, cocoa-nut oil, camphor, wax, pepper, and coarse cinnamon. It is well watered, and has the convenience of many rivers that are navigable for boats, and some for larger vessels.

PAPPENHEIM, a city of the kingdom of Bavaria, in the circle of the Rezat, which, with a district around it of seventy-seven square miles, inhabited by 7500 persons, forms a bailiwick, belonging to the mediatized count of that name, who, besides this, has other estates within the Prussian dominions. The city is situated upon the river Altmuhl, and contains the palace, two Lutheran churches, and 220 houses, with 1960 inhabitants.

PAPPUS, an eminent philosopher of Alexandria, said by Suidas to have flourished under the Emperor Theodosius the Great, who reigned from 379 to 395. His writings prove him to have been a consummate mathematician. Many of them, however, are lost; and those which remain continued long in manuscript, detached parts only having been occasionally published, until Carolus Manolessius published his remains entire at Bologna in 1660, folio.

PAPUA, or NEW GUINEA, a very large island, or, as some suppose, a cluster of islands, the coast having never been explored, and extending from the south end of Gilolo and the north coast of Ceram, in a south-west direction, about 1200 miles. It is indented by very deep bays, so that it resembles a chain of peninsulas; and it is because none of these inlets have been explored that it is uncertain whether it be all one island or a chain of islands. It is separated from the neighbouring island of New Holland by a narrow strait, discovered by Captain Flinders, in the Investigator. Viewed from the shore, Papua rises gradually into hills of considerable elevation; but there are no mountains of any great altitude. The country produces palm trees, and timber of a large size; the cocoa-nut, and the two species of the bread-fruit tree; also pine-apples and plantains, nutmeg trees in a wild state, and spice. The woods abound with wild hogs, which are hunted and killed by the natives with spears, and bows and arrows. The indigenous inhabitants of the interior practise gardening, and some sort of agriculture, and supply the inhabitants on the coast with food, in exchange for axes, knives, and other sorts of coarse cutlery. The Malays and Chinese chiefly carry on this traffic, supplying the natives also with blue and red cloths, and carrying back in return bark, slaves, ambergris, sea-slug, tortoise-shell, small pearls, and black and red loories, birds of paradise, and other birds, stuffed, in which art the Papuans are very dexterous. The island has chiefly been seen by navigators from the sea. Captain Forrest. who landed on the north-west coast, observed the structure of the Papuan dwellings, which was extremely singular, being built upon posts fixed several yards below the water-mark, and a long stage supported by posts communicating with the land just at high-water mark. The tenement contains many families, who live in cabins on each side of a common hall that runs through the middle of it, and has two doors, one opening to the land and the other to the water, for the purpose of facilitating the escape of the inmates when they are attacked by their enemies. The greater part of the inhabitants continue in their original state of barbarity and nakedness, devoid of any fixed homes, and subsisting on the precarious produce of the chase or of the forests. They are engaged in continual wars with their neighbours; and about April and March they assemble in great numbers, and make war on Gilolo, Ceram, Amboyna, and Ambloo. The British have had as yet but little intercourse with these savages; and their ferocious habits do not encourage any very close alliance. In 1791 they contrived to decoy the surgeon of the Panther, a Bombay cruiser, into their boats, where he was murdered; after which they had the audacity to make an attempt on the ship, discharging on it a shower of arrows, and wounding several of the crew. They were, however, soon dispersed by a discharge from the guns and small arms.

PAPYRUS, the reed from which was prepared the far-famed paper of Egypt.

Before entering on a description of the papyrus, it may be right to say a word or two as to the opinion generally received in Europe concerning the disappearance of this plant. Supposing the circumstance possible, the date of it must be fixed at no distant period; for it is not more than two centuries since Guilandin and Prosper Alpin observed the papyrus on the banks of the Nile. Guilandin observed the inhabitants of the country eating the inferior and succulent part of the stem, in the manner of the ancients; a fact which shows that it must have been the papyrus. This, and the practices related by Prosper Alpin, are sufficient to convince us that the plant is not wholly useless, although it is not now employed in the fabrication of paper. The alteration in the soil of Egypt, and the methods of agriculture, have in all probability rendered the plant less common; but causes altogether local could not occasion the destruction of the papyrus, especially as its residence in the marshes would prevent their operation. It is needless, however, to reason from probabilities or analogy. Mr Bruce not only saw the papyrus growing both in Egypt and Abyssinia, but actually made paper of it in the same manner as that in which it was made by the ancients. He tells us, likewise, that, so far from any part of it being useless, the whole plant is at this day used in Abyssinia for making boats, a piece of the acacia tree being put into the bottom to serve as a keel. That such were the boats of ancient Egypt, we know from the testimony of Pliny, who informs us that the plants were first sewed together, and then gathered up at stem and stern, and tied fast to the keel: *Conseritur bibula Memphitis cymba papyro.*

The papyrus, says Pliny, grows in the marshes of Egypt, or in the stagnant places of the Nile, formed by the overflowing of that river, provided they are not beyond the depth of two cubits. Its roots are tortuous, and in thickness about four or five inches; and its stem is triangular, rising to the height of ten cubits. Prosper Alpin states it as growing about six or seven cubits above the water; the stem tapering from the bottom, and terminating in a point. Theophrastus adds, that the papyrus carries a top or plume of small hairs, which is the thyrsus of Pliny. Guilandin informs us, that its roots throw to the right and left a great number of small fibres, which support the plant against the violence of the wind, and against the waters of the Nile. According to him, the leaves of the plant are obtuse, and resemble the *typha* of the marshes. Mr Bruce, on the other hand, assures us that it never could have existed in the Nile. Its head, says he, is far too heavy; and in a plain country the wind must have had too violent a hold of it. The stalk is small and feeble, and withal too tall; the root is also too short and slender to stay it against the violent pressure of the wind and current; and therefore it could never have been a plant growing in the river Nile itself, or in any very deep or rapid river, but only in the calishes or places where the Nile had overflowed and was stagnant.

The Egyptians made of this plant paper fit for writing (see PAPER), which they called βιβλος, or *philuria*, and also χαρτης, whence the Latin *charta*; for in general the word *charta* is used to signify the paper of Egypt.

The papyrus was produced in so great quantities on the banks of the Nile, that Cassiodorus compares it to a forest. There, says he, rises to the view, this forest without branches, this thicket without leaves, this harvest of the waters, this ornament of the marshes. Prosper Alpin is the first who gives us a plate of the papyrus, which corresponds in some degree with the description of the plant mentioned by Theophrastus; but by far the best drawing of it is that given by Bruce.

The ancient botanists placed the papyrus amongst the gramineous plants or dog-grass; ignorant of the particular kind to which it belonged, they were contented to specify it under the name of *papyrus*, of which there were two kinds, namely, that of Egypt, and that of Sicily. The moderns have endeavoured to show that these two plants are one and the same species of cyperus; and it is under this genus that they are found in the catalogues and descriptions of plants published since the edition of Morrison's work, where the papyrus is called *Cyperus Niloticus Syriacus maximus papyraceus.*

It is impossible to determine whether the papyrus of Sicily was used in any way by the Romans. In Italy it is called *papero*, and, according to Cesalpin, *pipero*. This papyrus of Sicily was cultivated in a garden at Pisa; and if we can depend on the authority of Cesalpin, who himself examined the plant, it is different from the papyrus of Egypt. The papyrus, says he, which is commonly called *pipero* in Sicily, has a longer and thicker stem than the plant cyperus. It rises sometimes to the height of four cubits; the angles are obtuse, and the stem at the base is surrounded with leaves growing from the root; and there are no leaves on the stem even when the plant is at the greatest perfection; but it carries at the top a large plume, which resembles a great tuft of dishevelled hairs. This is composed of a great number of triangular pedicles, in the form of reeds, at the extremity of which are placed the flowers, between two small leaves of a reddish colour like the cyperus. The roots are woody, about the thickness of reeds, jointed, and throw out a great number of branches, which extend themselves in an oblique direction. These are scented somewhat like the cyperus, but their colour is a lighter brown: from the lower part issue many small fibres, and from the higher a number of stems shoot up, which, in proportion as they are tender, contain a sweet juice.

The plume of the papyrus of Sicily is a tuft or assemblage of a great number of long slender pedicles, which grow from the same point of division, are disposed in the manner of a parasol, and carry at the top three long and narrow leaves, from which issue other pedicles, shorter than the former, and terminating in several knots of flowers. Micheli (*Nova Plantarum Genera*, Florence, 1728) has given an engraving of one of the long pedicles in its natural length. It is surrounded at the base with a case of about one inch and a half in height; and towards the extremity it carries three long and narrow leaves, and four pedicles, to which are fixed the knots of flowers. Every pedicle has also a small case surrounding its base. In short, the papyrus of Sicily is well known to botanists. It were to be wished that we had as particular a description of the papyrus of Egypt. It may be observed, however, that these two plants have a near affinity to one another; that they are confounded together by many authors; and that, according to Theophrastus, the *sari* and the *papyrus nilotica* have a decided character of resemblance, differing only in this, that the papyrus sends forth thick and tall stems, which being divided into slender plates, are fit for the fabrication of paper, whilst the *sari* has small stems, considerably shorter, and altogether useless for any kind of paper.

The papyrus, which anciently served to make paper, must not be confounded with the papyrus of Sicily, which is also found in Calabria. According to Strabo, the papyrus was not to be found anywhere except in Egypt and in India. The greater part of botanists have believed that the Sicilian plant is the same with the sari of Theophrastus; but others have alleged that the papyrus of Egypt and the sari were the same plant in two different stages of its existence, or considered with respect to the greater or less height; which, according to them, might depend upon the qualities of the soil, the difference of the climate, or other accidental causes. In proof of this, it is maintained, that there is an essential difference between the papyrus growing in the waters and the same plant growing on the banks of rivers and in marshes. The first of these has thick and tall stems, and a plume in the form of a tuft of hair very long and slender, and without any seed. The second differs from the first in all these particulars; it has a shorter and more slender stem, its plume is loaded with flowers, and consequently it produces seed. In whatever way we consider these facts, it is sufficient for us to know, that the difference between the papyrus and the sari neither depends on climate, nor soil, nor situation. The plants whose difference depended on these circumstances both grew in Egypt, and were both employed in the manufacture of paper. But it is an established fact, that the sari cannot be employed for this purpose.

Finally, the papyrus of Sicily began to be known by botanists in the years 1570, 1572, and 1583, at which periods the works of Lobel, of Guilandin, and of Cesalpin, first appeared. The ancients had no manner of knowledge of this plant, and Pliny makes no mention of it in his Natural History; from which it is evident that it was used neither in Rome nor in Sicily. If he had seen this plant, he must have been struck with its resemblance to the papyrus and the sari, as these were described by Theophrastus; and since he gives a particular description of the latter, he would most naturally have hinted at their conformity to the Sicilian papyrus, had such actually been the case.

PAR, in *Commerce*, signifies any two things which are equal in value. See EXCHANGE.

PARA, a province of Brazil, in South America, of immense extent, and of such surprising fertility that it is characterized as at once the paradise of the Indies and of Brazil. It is a region of endless luxuriance, one where every rood of ground would maintain its man; and sufficiently capacious to receive all the redundant population of Europe; for the dwellings of man are scattered over it so thinly that they have been compared to islands in a vast ocean. It is situated to the south and south-east of Guiana, being separated from it by the river Amazons. The river Madera, or Madeira, the great tributary of the Amazons, separates it on the north-west and west from the province of Solimoens and the territory of Peru. A line drawn nearly parallel with the ninth degree of south latitude separates it from the province of Matto Grosso on the south; Maranham bounds it on the east; and a considerable part of its northern limits is washed by the Atlantic Ocean. Its greatest length, from the Atlantic to the borders of Peru, is above fourteen hundred miles; at the broadest it is more than five hundred miles across, but it narrows towards either extremity, lying east and west. This vast tract of country is, to a considerable extent, a *terra incognita*, and it is supposed that at least two thirds of it are yet in possession of the aboriginal Indians. Cazal divides it into four large districts, viz. Para proper, a flat and wooded country, extending west of Maranham two hundred miles to the river Toccantines or Tocannos, which in this quarter traverses its whole extent from south to north; Xingutania, lying between the Toccantines and the river Xingu or Ghingu, which falls into the Amazons, near its mouth; Tapajonia, extending from the latter river to the Tapajos, which joins the Amazons about two hundred and twenty miles higher up than the Xingu; and Mundrucania, so designated from the Mundrucu Indians, who inhabit it, extending from the Tapajos to the Madera, which unites with the Amazons about the same distance above the Tapajos that the latter river is above the confluence of the Xingu. Indeed, in examining a good map of the country, nothing appears more striking than the manner in which the province of Para is divided into four portions by the rivers above named, all nearly of equal size, with the exception of Para proper, which is much smaller than the others. Of these rivers, the Amazons and the Madera have already been described in this work; and they constitute the leading hydrographical features of the country. The Toccantines is also a very large stream, in one part expanding to ten miles in breadth; and it is beautified with numerous islands. The Xingu and Tapajos are likewise considerable streams, originating in a cordillera of moderate elevation, which runs from north to south in the province of Matto Grosso. The upper courses of these rivers have never been explored, and the country which lies between them, and also between the Tapajos and Madera, where it joins with Matto Grosso, is consequently known only by the reports of the Indians. There are a number of other rivers, but none which requires specific mention, except the Annapu, which falls into the estuary of the Amazons between the rivers Toccantines and Xingu. Several islands lie at the mouth of the Amazons, one of which, called Majora, is a hundred miles in circumference, and so situated as to divide the river into two unequal branches. The island of Majora is a low, flat, alluvial formation, covered with brushwood and grass, and abounding in cattle and horses, with which it supplies Para. It is overrun with alligators, snakes, and wild beasts; and during the rainy season it is much flooded, and rendered very unhealthy when the waters have quitted it, and the sun has begun to exhale the malaria.

The geology of Para presents but little variety or novelty, and is precisely similar to that of Maranham. The soil upon which the city of Para stands is composed of clay and sand. The beds of clay are very extensive, and frequently thirty or forty feet in depth. There is scarcely any rock, and that only in particular and isolated masses; it is a coarse dark iron sandstone, with numerous particles of quartz imbedded in it. This is the only stone, and it is used as a building material. This species of sandstone, with fragments of white quartz, is observable at Maranham, and is the predominating formation at St Paul's, a little to the southward of Rio. The beds of clay at Para are of various qualities, some being admirably adapted for bricks, tiles, and coarse pottery; whilst others, again, are very fine, and capable of forming utensils which might vie in beauty with the celebrated Wedgewood ware. Beds of yellow ochre are abundant, and it is much in use for painting the houses externally. Limestone is imported from Portugal, granite from Rio, and slabs and sills from Europe. A gold mine is said to have been found in a mountainous hill on the coast near Selina No organic remains have as yet been discovered in these parts. The larger portion of the soil of Para is of extraordinary fertility, as will be seen by the account of the vegetable productions, remarkable alike for their variety and luxuriance. Situated immediately beneath the equator, the climate is hot and sultry; the thermometer averaging throughout the day from 84° to 89° in the shade. At night it occasionally falls as low as 75°, with very heavy and copious dews, particularly upon the river, drenching such boats as may be upon it, as if a shower of rain had descended. The river water is tepid, generally about 84°. As the air cools in the evening, it chills the surface of the water, and in doing so a humid vapour is emitted. There is no difference of temperature throughout the year, the mean degree of heat being 84°. There are two seasons, the wet and the dry. The rainy season commences in the latter part of December, and continues until July, raining more or less every day, without intermission, for many hours. The air continues sultry and oppressive, with light variable winds, and occasional squalls from various points of the compass, accompanied by thunder and lightning of the most appalling description, whilst the rain at the same time descends in torrents. The thunder-storms take place most frequently in the afternoon, about two or three o'clock; and the same is observable at Rio and other places. It generally begins to rain about eleven o'clock in the forenoon, and continues until nine or ten at night. The country is flooded in many parts during this season, and vessels are often detained several weeks, not being able to take on board their cargoes. The dry season at Para occupies the remaining portion of the year, from July to December. But even during this period rain frequently falls, and thunder-storms occur in the afternoon. This is also the peculiar season of winds, which blow fresh from the north-east during the day, with a light breeze only in the evening. Lightning is frequent in the horizon every night. Of course the days and nights in this "region of the sun" are nearly of equal length throughout the year. For a country situated within the torrid zone, Para cannot be considered as unhealthy, although it was formerly reckoned so. But since the woods were thinned, and cattle were introduced, a material improvement has taken place. It is exempted from endemic diseases; but intermittent fevers or agues attack those who have newly arrived in the country, and they become more common as the river is ascended. Those employed in the gathering of sarsaparilla are very frequently attacked with fever, and numbers of the natives die of it. Dysentery, tetanus, and some other diseases, common to various parts of Brazil, prevail in Para. In 1825, the small-pox is said to have carried off five thousand persons in the capital.

This province is unusually rich in vegetable productions, particularly such as are called, *par excellence*, botanical. There is an inexhaustible supply of timber of the very best quality, and almost of every variety, so that there is abundance of fuel. The palms are amongst the most conspicuous and useful products of the vegetable kingdom. They afford the inhabitants food, drink, and even raiment; for the pith of some of these species of trees produces an edible substance resembling sago, the pericarp of others yields a pleasant beverage, and the leaves afford a covering for houses, as well as materials for making hats and baskets. Some furnish them with oil; and canoes and boats are hollowed out of the trunks of others. The palms are of various species; one, called the areca, reaches a hundred and thirty feet in height. Indeed there is to be found here timber for every purpose for which man can require it, from the soft cork-wood of the *ochroma sayopus*, to the dense hard iron wood. There is the *cedrela odorata*, or soft cedar wood, very handsomely veined; the white cedar or *bignonia leucoxylon*, and an abundance of other bignonias; the balsam copaiva tree, which affords good timber, besides its medicinal product; ornamental woods of every hue and grain, including rose-wood, satin-wood, yellow wood, ebony, and others; the *bertholletia excelsa*, a lofty spreading tree, producing a woody capsule three inches in diameter, so heavy, hard, and solid that it requires a powerful blow of a sledge-hammer to break it (the bark of this tree, when beaten into flakes, is used in place of oakum or hemp); the *lecythis ollaris*, or pot-tree (so called from the seed-vessel resembling a rusty iron pot with a lid), the nuts of which are esteemed as of a very superior quality, and are sent as presents from the interior; the *carapa guareoides*, or anderaba, the seeds of which yield an oil that is put to a variety of uses, and amongst others as a lamp-oil, and for making soap; the calabash, which furnishes the natives with many utensils; excellent woods for ship-building, equal to the teak of India; and a vast variety of trees and plants which yield dye-stuffs of the finest quality. Amongst these may be mentioned arnotta, of which there are three species; indigo; crajaru, or the juice of a plant (*bignonia*), formed into cakes of a bright red. It is prepared by the Indians, and is a capital and very durable oil colour. The *amomum sylvestre* yields a blue colour. Para is exceedingly rich in oils, including turtle-oil, procured from the fat of the turtle. Turtles frequent the upper part of the river in immense numbers; and no less than six thousand jars of their oil, each containing seven gallons, are annually received at Para. Besides these, may be mentioned the azeite mammona, or castor oil, for lamps, and common lamp-oil; the unctuous substance of cacao, which is used in the manufacture of soap; a fine sweet oil resembling that of the olive, obtained from the patacia, a species of palm; the bacova, a species of palm oil; the common cocoa-nut oil; and that of the anderaba, already mentioned. These oils can be procured in the greatest abundance, at a very cheap rate, and may be rendered an object of considerable commercial importance. Amongst the medicinal plants and drugs are sarsaparilla, balsam copaiva, tonquin beans, procured in vast quantities, and which yield, by distillation with spirits or with water, an odorous essential oil; arnotta vanilla, which perfumes the woods, and creeps up the trees like a large and elegantly-leaved ivy; gum copal of a spurious quality; gum caju, or the gum of the cashew apple; the pod of the *cassia fistularis*, and the leaves of several of the cassias, which are as good as senna; the *portlandia hexandria*, which is an emetic, a cathartic, a febrifuge, and a tonic; the *mirabilis jalapa*, or the jalap of the country, very common in Para; besides many others, which it is unnecessary to enumerate. Not a few of the trees of this province yield a milky juice, the fig-trees in particular, and they are very numerous. One of the most remarkable of these is the *vaccodendron lactifera*, or milk-bearing cow-tree as it has been called, from its extraordinary property of yielding milk, similar, it is said, to that of a cow. The tree is one of the loftiest in the forest, being above a hundred feet in height. The fluid which it yields appears to bear the nearest resemblance to animal milk of any vegetable product. It is a rich white bland fluid, without odour, and of the taste and flavour of common milk, as a substitute for which it is extensively used. Amongst the useful and curious products of the province, the *siphonia elastica* or cahuchuc requires particular mention. It is the tree which produces the well-known elastic gum or India rubber, and is amongst the largest of the forest. It abounds to such an extent as to form one of the staple articles of commerce, and Para is the great emporium for supplying Europe with this article. Very strong and durable shoes, and other articles of wearing apparel, are manufactured from it. Amongst the spices and aromatics, this province produces turmeric, ginger, black pepper, cayenne, native nutmeg, *laurus cinnamomoides*, clove bark (having precisely the flavour of cloves, and used as such), some aromatic amomums, several species of pepper, piper amalayo, and ginger pepper. There are also laurels, cinnamon, cloves, and allspice cultivated for sale; and the tobacco raised is reported to be the genuine Orinoco.

Para yields great abundance of fruits, and also of farinaceous grains and roots. Rice, Indian corn, and the favourite mandioc root, supply the inhabitants with flour and tapioca. Cocoa is plentiful, and coffee and sugar are cultivated for exportation. Amongst the fruits of the province are several varieties of the most exquisite pine-apples, remarkably large and fine oranges, limes, sweet lemons, custard apples, cherimoyas, alligator pears of an immense size, very fine quality, and forming a part of the food of the common people; the fruits of the passiflora, tamarinds, guavas, pawpaws, superb melons, plantains, and bananas, mangoes in profusion, several species of the achras, and palm drupas; the bucari, ingas, rose-apple, bread-fruit, and jacks; figs, sapodillas, abiu, macoubea, and abricot, similar in flavour to the apricot. There is a small crop of grapes three times a year. The marauta, or arrow-root genus, affords several edible roots; and, with regard to vegetables, there are abundance of cucumbers, pumpkins, lettuce, chilis, potatoes, cabbages, a variety of beans, yams of several kinds, tomatas, and the egg-apple, besides others. Without adverting to the Flora of this province, farther than stating generally that it is exceedingly beautiful and various, the foregoing account of the vegetable kingdom of Para will sufficiently show that, in the abundance, variety, and luxuriance of its products of this description, it is not surpassed by the most favoured spots upon the globe.

Para is equally prolific in wild animals, abounding in monkeys, snakes, and lizards. The vampires fly about at night in great numbers, and are exceedingly annoying; and the vampire bat, in particular, is notorious in the country for its blood-sucking powers. The guano tribe is numerous, but harmless and timid as hares; and there are numbers of tapirs and ounces. The river-banks are infested with alligators, the island of Marajo being their rendezvous. The electrical eel attains to a considerable size, and sometimes kills a horse that is wading in the streams. Such is its power, that by one stroke of its body it knocks the animal down and kills it. There is an abundant supply of fish, both from the river Amazons and from the ocean; but they do not keep well. The dorado is the most esteemed. There are two large fishes of the silurus kind, which yield isinglass; but a better sort is procured from the gurujuda, a fish somewhat like a sturgeon in appearance, and caught at the mouth of the river. The pereiba is a very large fish, from five to six feet in length, and of a shark-like aspect. The pirarucoa is likewise a very large fish, which the inhabitants salt; and there are various kinds of small fish, which it is unnecessary to enumerate. The birds of these regions are well known, being famous for their beauty and splendour; and insects are so multitudinous that, according to a writer who has visited the country, "the ants alone would be the labour of a person's life to detail; in every fruit, on every flower, there is almost a peculiar ant."[1] Fire-flies sparkle beautifully at night amongst the trees and bushes, flashing their meteoric wings, and then vanishing in a moment. Some of the spiders are extremely large and venomous; and Para is noted for snakes, amongst which is the gigantic boa-constrictor, that kills an ox and immediately gorges the animal.

Capital.

The city of Para stands on a low part of the right bank of the eastern branch of the river Para, about fifty miles from its mouth. As seen from vessels in the river, it presents nothing particularly attractive or conspicuous except its numerous churches. No lofty ranges of buildings are to be seen in this city of the western world; and, being environed by wood and the waters of the river, and built on somewhat low ground, it has altogether a humble appearance. It extends about two thirds of a mile along the Para, and is about half a mile in breadth; the highest point of ground, that on which the church of St Anne is situated, being about seventy feet above the surface of the river. Directly opposite to it, and about two miles distant, is the large island of Oncas, with several smaller ones lower down the river. Rather more than a league below the city there is an insulated rock, on which a fort called Serra is built, and to which all vessels inward or outward bound are obliged to send a boat with papers before they are allowed to proceed to or depart from the city. Somewhat less than a league above the city is the mouth of the river Guama, up which passengers to Maranham are said occasionally to proceed in an easterly direction, and, crossing a narrow neck of land, embark in boats on the sea, keeping close in along the coast. It is probably on account of the facility which this and other rivers, particularly the Toccantines, afford for a communication with the interior of Brazil, that the present site of Para was chosen. Between the mouth of the river Guama and the city there is the naval arsenal, at which large vessels are built. The city is protected by two forts, both placed on steep and rocky but not elevated points. The streets of Para are laid out at right angles to each other, but they are not remarkable for their breadth, and only some of them are paved. The houses in general are about two stories high, and well built, having latticed blinds for windows, which adds to the sombre appearance of the city Para has little of that bustle of business observable in most commercial towns, but is dull, noiseless, and cheerless. The principal building in Para is the palace, a large square, two stories in height, having an open balcony at the second story, ornamented with large wooden figures at the outer part, and palm-trees between the windows. Several of the government offices are in the palace, and it is the abode of the president. Internally it is well but not gaudily fitted up; and altogether it is a handsome and commodious building, every way worthy of the purpose to which it is appropriated. On the north, east, and west sides the ground is open, and there the troops were wont to be paraded every morning. Adjoining the palace are the walls and several arches of what was intended for a theatre; but although the design was good, the whole has proved a failure. There are a cathedral and eight churches; and there either are or were four or five convents. The cathedral is built in the form of a Latin cross; and its structure and decorations, without being gaudy, have a pleasing effect. The interior is neat, and is of sufficient size to accommodate a large audience. The bishop's palace is in the cathedral square, and stands opposite to that building. It is a large and plain but respectable edifice; and appended to it is a church or chapel for the domestic service of the bishop and his establishment. In the same square there is a comfortable hospital. The remaining part of it is filled up with dwelling-houses. In the middle of the city is the church of St Anne; close to the water is the church of Los Mercez, and adjoining to it are the custom-house and the prison. These three form the most conspicuous range of buildings in the city, but they are nevertheless by no means remarkable. The custom-house is large, well built, and apparently commodious. It has a distinct quay, with a broad flight of wooden stairs leading to it; and immediately opposite to it stands one of the forts.

The streets of Para have little or nothing that is attractive about them. The shops and warehouses are numerous, and are tolerably well supplied with merchandise; but there is a deficiency of taste and elegance in their arrangement. The markets are held close by the water-side, near the church of Mercez, where women with vegetables and fruit congregate for the most part of the day; but butcher-meat is not to be obtained after ten in the forenoon, a very salutary regulation, on account of the great heat of the place. Cattle and horses are brought from Marajo and some of the neighbouring islands, where they run wild, but belong to individuals, some of whom are the proprietors of whole islands, and all the cattle upon them. The horses are not large nor powerful; and in the wild state they are valued at about five dollars each. They are occasionally exported to the islands of the West Indies. Although Para possesses few attractions as a city, the environs contain numerous beautiful shady walks and cool retreats. There is one public walk in the city, much resorted to in the evening, for the delightful promenade which it affords. The others are principally formed by rows of lofty silk-cotton trees, which bear no little resemblance to the elegant horse-chestnut of Britain. The country in the immediate vicinity of Para is very beautiful, and the outlets to it are abundant. In the suburbs of the city there are several elegant little villas, with extensive gardens attached to them, rich in all the varieties of tropical produce. The road to the Nazaré church, distant about a mile from the city, is a favourite resort of the people of Para. The church, which is built on a small scale, like that of a village, is simple and neat, and most romantically situated on the skirts of a wood, with a small open area in front. Here, in the month of October, a scene of grand festivity takes place, called the fair of St Nazaré, over which the clergy preside, and it is attended by every inhabitant of Para. Frolic and feasting, the usual business of fairs, with the general custom of gambling, continues for a fortnight, and the scene closes with high mass, performed in the most imposing style. Para is lamentably deficient in public institutions for education. The whole town can only boast of one school, which is under the direction of the clergy. There is not, it is said, a bookseller's shop in Para; so that gross ignorance is the rule, not the exception. There is indeed a weekly gazette published, but it is chiefly as a channel through which the edicts of government are circulated. The laws are bad, and they are also badly administered; indeed justice is so tardy, that criminals may sometimes lie in prison till they rot, before being brought to trial. Para stands in longitude 48. 39. 45. west from Greenwich, and latitude 1. 28. south.

---

[1] Narrative of a Voyage to the Southern Atlantic Ocean during the years 1828, 1829, and 1830; extracted from the private journal of W. H. B. Webster, surgeon of the vessel (vol. ii. p. 363). For further particulars regarding the vegetables and animals of Para, the reader is referred to this work, from which the account in the text is chiefly taken.

Notwithstanding the natural riches and the superabundant advantages of Para, it is a very poor city, and receives a subsidiary stipend from the neighbouring province of Maranham, amounting to L.8000 annually, to defray the expenses of its government. In consideration of this gratuity, Para receives the goods imported into Maranham duty free, and likewise defrays the expenses of the packets and men of war on the station. The currency of the province is a good criterion of its general poverty. Copper is the only circulating medium, and even that is of the basest description. Besides, it is, or at least was a few years ago, liable to be called up by the government at pleasure, and restamped, by which operation it became of twice its former value. "It would appear," says Mr Webster, "that this province is the very sink of the empire in respect to currency, as all the base copper coin which is not passable in the other parts of the empire finds here a ready circulation. No better idea of it can be given than the fact, that what passes for one hundred pounds in copper coin, is really and intrinsically worth only eight pounds. Silver was at a premium of twenty-five per cent.; and the very sight of a dollar, when we were there, was quite a rarity. Hence the necessaries of life are cheap. House-rent is moderate, and there are no direct taxes." In mentioning the price of articles, this writer observes, that "horses are worth sixteen shillings each, and are generally fed with rice chaff. Foreign produce is by no means high at Para, the wines of Portugal and the manufactures of England being comparatively cheap." With regard to trade, he observes, "it is said that it was the miserable policy of the Marquis de Pombal, not only to keep foreigners, but the Portuguese themselves, ignorant of the value of this province; a policy which was realizing the character of the dog in the manger illustrated by the fable. He did every thing in his power to degrade and keep it in the back ground. The situation of it is well adapted for rendering it the dépôt of an extensive and lucrative trade; but the commerce, in consequence of such short-sighted policy, is extremely small, a kind of petty retail rather than any extensive or liberal trade. A merchant is obliged to buy, from time to time, small scraps and parcels; such, for instance, as a pound or two of isinglass, by which means he is long in accumulating a stock." All the produce is brought to Para in canoes, from a distance of six or seven hundred miles in the interior. Cocoa is the staple article of commerce, and it is produced in vast quantities; but being now so much depreciated in the foreign markets, it will not defray the expense of freight. There is, in fact, no demand for it, and the aroba, or thirty-two pounds of cocoa, is sometimes worth only twenty pence. Rice is very abundant, but cotton is scarce. Sarsaparilla, which is principally exported to Lisbon, and thence to London, balsam copaiva, tonquin beans, vanilla, farina, oils, and Indian rubber, are the chief articles of exportation. Those principally imported consist of flour, spermaceti candles, soap, shoes, and other goods, from the United States; cotton goods and hardware from England; and wines, vinegar, olive oil, limestone, drugs, chestnuts, and some few other articles, from Lisbon. The manufactures of Para are ladies' combs, polished with the leaf of the *curatella Americana;* good leather, made of the skins of the goats or hares of the country; coarse and bad pottery; chocolate, coarse hammocks, straw and palm hats, lace, salt-fish, and jerked beef. The Indians bring down from the interior elegant wands of beautiful feathers, called sceptros, besides superbly ornamented hammocks, feather dresses, bows and arrows, and stained calabashes. The Brazilian tribes about Para appear to be a very fine, healthy, and well-conditioned race of people. Their skin is of a good firm copper colour, without a tinge of black; they have long jetty hair, with rubicund faces and intelligent features, in which a general expression of mildness predominates. "The superiority of the Brazilians over the poor African tribes of slaves at Para," says Mr Webster, "is particularly remarkable; and the contrast is sadly against the latter. It is customary for the negro slaves to come down in groups every morning to the riverside, to purchase various articles of produce brought down from the interior by the native canoes. At this usual morning rendezvous, some bring coffee ready made for breakfast, while others bring a favourite liquor called 'wassaree,' an infusion of a small kind of palm. This beverage has the colour of port wine, and when sweetened is highly esteemed by these people. In fact, with a banana, or alligator pear, it forms the principal fare of many, while others prefer the farina of the cassada with it." The city of Para was built by the Jesuits in the year 1615, and, before the revolt of the negroes, contained about 20,000 inhabitants. The population of the entire province was estimated in 1830 at 190,000.

The only other town of any consideration in Para proper is Bragança, formerly Cayte or Cahete, and the capital of a short-lived captaincy. It is distant about twenty miles from the sea, and nearly one hundred miles east-north-east of Para. It is a port at which coasters touch on their way from Maranham to the capital, and is one of the oldest towns in the province, with a population of about 2000 inhabitants. Villa Vicoça, or Cameta, is the largest town in the whole province next to Para. It is situated on the left bank of the Toccantines, about forty miles from its mouth, and ninety miles south-west of the capital, with which it has a distinct water communication, by means of a natural canal, navigable with the tide. This place is a mart between Para and Goyaz, and contains about 6000 inhabitants. The river Toccantines here expands to ten miles in breadth, and the tide extends twenty-six leagues higher up, to the registry of Fort Alcobaça, the navigation being thus far uninterrupted by either rocks or rapids.

The colony of Para was originally an offset from that of Maranham. In the year 1615, Francisco Caldeiro sailed from St Luiz with two hundred men in three caravels, intrusted with the project of selecting an eligible situation for a settlement more immediately within the vicinity of the river Amazons, with a view to promote the navigation of that river, and to frustrate the attempts of any other nation to form settlements in this direction. The Dutch at one time had establishments upon both banks of the river, but they were expelled by the Portuguese about the year 1622. The early history of the province exhibits the same nefarious system of slave-hunting that was practised in almost all the captaincies; but it was carried on in Para with peculiar cruelty. An end, however, was at length put to the captivity of the Indians, none but negroes being permitted to be sold as slaves; and under the Jesuits the population became more numerous than that of the eastern provinces. The evil consequences of their expulsion were more perceptible here than in any other part of Brazil, says Mr Southey, "because nowhere had so many *aldeias* been established, nor had they anywhere else been in so flourishing a state." The city of Para was recently the scene of a fearful revolt of the native Indians. The cause of quarrel was the confinement of an Indian charged with having committed some offence. His brother, having vainly solicited his liberation, assembled a body of about three hundred of his countrymen, and attacked the city on the 14th of August 1835. The assault was at first unsuccessful, and the contest continued for several days without any result; but the insurgents having gradually gained possession of the most favourable positions, the inhabitants were seized by a panic, and the Indians, rushing in through the by-lanes and narrow streets, commenced an indiscriminate slaughter, at the same time sacking and pillaging the city. An expedition sent against them proved unsuccessful; but they voluntarily abandoned the city, and the imperial troops entered it on the 13th of May 1836. When Para fell into the hands of the insurgents, it was said to have contained British property to the amount of L.300,000, but after the capture of the place scarcely a vestige of it remained. (R. R. R.)

PARABLE, a fable or allegorical instruction, founded on something real or apparent in nature or history, from which a moral is drawn by comparing it with something wherein the people are more immediately concerned: such are the parables of Dives and Lazarus, of the Prodigal Son, of the Ten Virgins, and others. Dr Blair observes, that of parables, which form a part of allegory, the prophetical writings are full; and if to us they sometimes appear obscure, we must remember, that in those early times it was universally the mode throughout all the eastern nations to convey sacred truths under mysterious figures and representations.

PARACATU, a comarca of the province of Minas Geraes, in Brazil, South America. This district, which was detached from Sabara, and formed into a separate comarca in 1815, comprehends all the country lying to the westward of the river St Francisco, from the Carinhenha to the Abaité. Cazal states that the latter river is formed by two streams of the same name, one coming from the south-west, the other from the north-west, their sources being nearly one hundred miles apart. The intervening territory is a forest tract, called Matto da Corda, enclosing several campinhas, or extensive grazing lands. The principal heads of the Paracatu are the Escuro and the Prata. The latter is said to have yielded some fine diamonds, and it was customary for a strong guard of soldiers to patrol its banks. Twenty miles north of the confluence of the Paracatu, the St Francisco receives the large river Urucuya. At almost an equal distance between the mouths of these two rivers is the considerable arraial of St Româo, which carries on an extensive inland trade, especially in salt, obtained from Pilâo Arcado and its vicinity. Above the mouth of the Urucuya the St Francisco receives on its western margin a number of rivers, on most of which there is a parish or arraial, but immense tracts of country are wholly unappropriated. On the banks of the St Francisco, and to the eastward, great numbers of cattle are bred, and large herds are sent to Rio, a distance of above six hundred miles. The want of salt in these parts is a serious evil, as it is requisite for the cattle; nor will they, it is said, breed well without it. The river Abaité is distinguished by having produced the largest diamond that was ever found in America. It weighed nearly an ounce, and was accidentally discovered by three outlaws when searching for gold. This spot has since been wrought at different periods with various success; but although large diamonds have been found, their quality has been indifferent, and the works are now abandoned. Paracatu do Principe, the only town in the district, owes its origin to its mines, which were first discovered in 1744. A great number of adventurers were lured to the spot by the quantity of gold found, and the Indians were expelled from their native territory. The town, however, has very much decayed. The gold is of a good colour, but of indifferent quality, and difficult of extraction, from the want of water. Diamonds having subsequently been discovered in various parts, the working of the gold-washings is now restricted to a few leagues round the town. The town has the advantage of a healthy situation, upon an elevated plain. The houses are of taipe; the streets are paved; and, besides the church, there are four hermitages. In the neighbourhood, the vine, the orange, and the pine-apple flourish luxuriantly, and there is abundance of deer and game. The town contains above one thousand inhabitants, but of the population of the district no correct estimate can be formed.

PARACELSUS, Philippus Aureolus Theophrastus, a famous alchemist and enthusiast of the sixteenth century, was born in 1493, at Einsiedeln, a small town of the canton of Schwitz, distant some leagues from Zurich. His father, who practised medicine at Villach in Carinthia, was a near relative of George Bombast de Hohenheim, who afterwards became grand-prior of the order of Malta; so that Paracelsus was not sprung from the dregs of the people, as his sworn enemy, Erastus, pretends. His early education appears to have been neglected, and he passed a part of his youth leading the life of a strolling schoolman of that period; in other words, he wandered from country to country, predicting future events by inspecting the stars and the lines of the hand, conjuring up the dead, and repeating various operations in alchemy and magic, into which he had been initiated either by his father, or by different ecclesiastics, amongst whom he mentions the abbot Trithcim, and several German bishops. As Paracelsus everywhere shows himself ignorant of the most common and elementary parts of knowledge, it is not probable that he had ever seriously studied in the schools. He contented himself with visiting the universities of Germany, France, and Italy; and although he boasts of having been the ornament of these schools, there is no evidence of his having legitimately acquired the title of doctor, which he chose to assume. All we know is, that he laboured for a long time in the house of a certain rich man, named Sigismond Fugger de Schwatz, in order to learn from him the secret of the philosopher's stone. According to the usage of the alchemists, Paracelsus travelled into the mountains of Bohemia, Sweden, and the East, to inspect the labours of the miners, get himself initiated into the mysteries of the oriental adepts, and observe the wonders of nature, particularly the celebrated magnetic mountain. He is also said to have traversed Spain, Portugal, France, Prussia, Poland, and Transylvania, communicating not only with the physicians, but also with the old women, quacks, and magicians of these different countries. It is even believed that he extended his travels as far as Egypt and Tartary, and that he accompanied the son of the Khan of the Tartars to Constantinople, in order to learn of a Greek who resided in that capital the secret of the tincture or elixir of Trismegistus. This vagabond life naturally left Paracelsus very little time for reading; and, in fact, he has himself stated, that during the space of ten years he did not open a single book, and that all his medical library consisted of about a dozen pages. Nor did his desire of knowledge increase with his years; for an inventory made after his death shows, that the only books which he left behind him were a Bible, a Concordance, a New Testament, the Commentaries of St Jerome on the Gospels, a volume on medicine, and some seven manuscripts.

It is not known at what period he returned to Germany; but it appears that, about the age of thirty-three, several remarkable cures, which he wrought on persons of distinction, gave him such celebrity, that in 1526, he was, on the recommendation of Œcolampadius, called to fill the chair of physic and surgery in the university of Basil. Here Paracelsus commenced his career by burning publicly in the hall the works of Avicenna and Galen; assuring his auditors, that his shoe-ties knew more than these two physicians, that all the universities, and all the writers united, were less instructed than the hairs of his beard, and that he should be regarded as the sole monarch of physic. The novelty of his doctrine, the confidence with which he spoke of his success, the power to which he pretended of prolonging life, and curing the most inveterate diseases, and the use of the vulgar tongue in his discourses, attracted to Basil a crowd of credulous persons, equally indolent and enthusiastic. The prelections which he delivered on practical medicine have fortunately been preserved; they are in a mixed jargon of German and barbarous Latin, and contain nothing but a multitude of empirical remedies, indicated with the greatest pretension. So much impudence, however, far from diminishing his renown, served only to increase it, insomuch that Erasmus, who had long suffered from gravel, applied to Paracelsus; and this circumstance led to a correspondence (which has been preserved) between these two men, who enjoyed such opposite kinds of celebrity. But even at Basil people soon began to discover that the new professor was an impudent and presumptuous quack. Scarcely had a year elapsed when his prelections were deserted. As soon as the novelty wore off, his jargon was found to be incomprehensible, and his empiricism a mere cloak for ignorance. But what contributed more than any other cause to ruin his reputation was the crapulous life which he led. According to Oporin, who lived two years with him, he almost never appeared in his lecture-room without being half drunk, and seldom dictated to his secretaries except under the influence of wine. If called to visit a patient, he rarely did so without having first gorged himself with liquor. He had the custom of sleeping in his clothes, and sometimes passed whole nights in low taverns drinking with peasants, so that in the morning he had not the slightest recollection of what had passed during the night. On one occasion, however, having exceeded the ordinary license of his orgies, he assailed a magistrate with the grossest abuse; and, dreading punishment for such an outrage, found himself under the necessity of decamping from Basil, towards the end of the year 1527. He took refuge in Alsace, whither he was followed by his secretary Oporin, with all his chemical apparatus, and then resumed the same kind of strolling life which he had led in his youth.

Being thus cast loose again upon the world, he appeared at Colmar in 1528, at Nuremberg in 1529, at Saint-Gall in 1531, at Pfeffers in 1535, and at Augsburg in 1536. He then made some stay in Moravia, where he once more compromised his reputation by the loss of some distinguished patients, and was in consequence obliged to take his departure for Vienna. From that capital he passed into Hungary, and, in 1538, appeared at Villach, where he dedicated his *Chronicle* to the states of Carinthia, in gratitude for the favours which they had bestowed on his father. But his stay here appears to have been short; for, in 1540, we find him at Mindelheim, whence he proceeded to Saltzburg, the ultimate term of all his wanderings. On the 24th of September 1541 he died in the hospital of St Stephen at that place, in the forty-eighth year of his age, and in a state of abject poverty; notwithstanding he pretended to the possession of the double secret of transmuting metals, and prolonging life even to the extent of several centuries.

The life of this man forms a curious chapter in the history of self-delusion and imposture. Yet in order to judge rightly of Paracelsus, as well as of the reform which he wished to effect in medicine, it is necessary to dismiss all prejudice, and to disregard alike the hostility of Erastus and the exaggerations of Murr. It is also proper to keep in view the predominant spirit of the age in which he lived, and to remember that this epoch was famous for the reign of astrology and alchemy, the abuse of all sorts of superstitious practices, the apparition of spectres, ghosts, and hobgoblins, frequent demoniacal possessions, and the juggleries of a crowd of seers and fanatics, who, throughout all Europe, and particularly in Germany, practised on the credulity of the people. Such were the causes which prepared the way for the system of Paracelsus, and inflicted a severe blow on that of Galen. To speak in a vulgar language, to write rather for the people than for the learned, to introduce the cabbalistical art into medicine, as a substitute for that knowledge which is only acquired by study, to employ a crowd of mystical and barbarous terms, which make the greater impression on the multitude the less they are understood; such were the means of which Paracelsus availed himself, and which, but for his own indiscretion and misconduct, would most probably have been attended with triumphant success.

His philosophical and medical system is curious, even by reason of its absurdity. He takes as his primary supports religion and the sacred books. He assures us that the contemplation of the perfections of the Deity is sufficient to procure all knowledge and all wisdom; that the Holy Scriptures conduct to all kinds of truth; that the Bible furnishes a key to the theory of diseases; and that magical medicine can only be learned by the study of the Apocalypse. The man who blindly obeys the will of God, and who succeeds in identifying himself with the celestial intelligences, possesses the philosopher's stone; he can cure all diseases, and can prolong his life at pleasure, because he holds in his possession the tincture which Adam and the patriarchs employed before the Deluge to prolong the term of human existence to eight or even nine centuries. Paracelsus professed the grossest pantheism. He admitted the existence of pure spirits without souls. According to him, all beings, even the minerals and fluids, take aliments and drink, and expel fæces. His physiological theory, a confused mass of the most incoherent ideas, is founded on the application of the law of the cabbala to the demonstration of the functions of the human body. The Sun has an influence on the heart, the Moon on the brain, Jupiter on the liver, Saturn on the spleen, Mercury on the lungs, Mars on the bile, and Venus on the kidneys and the organs of generation. Before attempting to explain the functions, or to cure diseases, the physician should know the planets of the microcosm, their meridian, their zodiac, their rising and setting; and it is by means of this knowledge that he attains to the discovery of the most hidden secrets of nature. The body is formed by the concourse of sidereal, that is, immaterial salt, sulphur, and mercury. Each of the elements may admit of all qualities, so that there may be dry water and cold fire. Another of his doctrines related to the *archeus*, a species of demon, which performed in the stomach the function of an alchemist, separating the poisonous matter contained in the aliments from that which serves the purpose of nutrition.

Nor was Paracelsus less absurd in his pathological theory. Returning always to magic, he assures us that it is the art of arts, and that from it all knowledge of medicine must be derived. He glories in passing for a magician, and even boasts that he had received from hell letters written by Galen, and had maintained, in the vestibule of that dreary region, keen disputes with Avicenna on portable gold, the elixir of the philosophers, the quintessence, the mithridate, and the philosopher's stone. He attributes diseases to five general causes, which he names *entities*, and which have relation to the astrological system; so that, instead of observing symptoms, a physician should consult the planets, in order to distinguish if the entity be divine, or astral, or natural, or spiritual, or poisonous. He declares that there is an essential difference between the diseases of men and those of women, because the *uterus*, as a microcosm within a microcosm, performs an important part in all the affections of women. To the menstrual blood he attributes the most extraordinary properties, particularly a poisonous quality. He explains each malady in particular by the help of his three principles of chemical entities, which he substitutes instead of the four elements of the ancients. In therapeutics and in materia medica his theory is altogether cabbalistical. He regards gold as a specific in all cases where the heart is the primary seat of the malady; recommends the study of anatomy and chiromancy in order to discover the virtues of vegetables; and states that, before employing any medicament, it is indispensable to observe the state of the constellations. In surgery he altogether rejected the use of cutting instruments, caustics, and even sutures, and pretended to cure fractures without bandages, by means only of comfrey. He employed the magnet in cases of hæmorrhage, hysteria, epilepsy, and the greater part of the spasmodic affections; and extended more than ever the abuse of talismans. But amidst all this absurdity and extravagance, Paracelsus had the undoubted merit of attempting to introduce into medicine the use of antimonial, mercurial, and ferruginous preparations, which have so efficacious an action upon our organs; and it is equally certain that alchemy, which ruined so many adepts, proved advantageous to the medical sciences, by reason of the important discoveries which incidentally resulted from the numberless experiments made by its professors.

Paracelsus published very few works in his lifetime, and those which are attributed to him exhibit so many contradictions that several of them have been ascribed to his disciples. It would be a useless waste of space to enumerate the titles of all his works; we shall therefore content ourselves with indicating the different complete collections. 1. The German editions, Basil, 1575, in 8vo, ibid. 1589–1590, in ten vols. 4to, and Strasburg, 1603–1618, in four vols. folio; 2. The Latin editions, *Opera Omnia Medico-Chymico-Chirurgica*, Francfort, 1603, in ten vols. 4to, and Geneva, 1658, in three vols. folio; 3. The French editions, *La Grand Chirurgerie de Paracelse*, Lyons, 1593 and 1603, in 4to, and Montbéliard, 1608, in 8vo. (See Adelung, *Histoire de la Folie Humaine*, tom. vii.; the *Biographie Universelle*, article Paracelse; and Sprengel, *Histoire Pragmatique de la Médécine*, tom. iii.) (A.)

PARACLETE, the COMFORTER, a name given to the Holy Spirit.

PARADANGA, a town of Bengal, in the district of Cooch Behar, and pleasantly situated on a small river, thirty-three miles north-east of Rungpore.

PARADISE, a term principally employed to signify the garden of Eden, where Adam and Eve were placed immediately upon their creation.

There have been many speculations as to the situation of the terrestrial paradise. It has been placed in the third heaven, in the orb of the moon, in the moon itself, in the middle region of the air, above the earth, under the earth, in the site occupied by the Caspian Sea, and under the arctic pole. The learned Huet places it upon the river formed by the junction of the Tigris and Euphrates, now called the *River of the Arabs*, between this junction and the division made by the same river before it falls into the Persian Gulf. Other geographers have placed it in Armenia, between the sources of the Tigris, the Euphrates, the Araxes, and the Phasis, which they suppose to be the four rivers described by Moses. But concerning the exact place we must necessarily be very uncertain, if indeed it can be thought at all to exist at present, considering the many changes which have taken place on the surface of the earth since the creation.

"Learned men," says Mr Miln, in his *Physico-Theological Lectures*, "have laboured to find out the situation of Paradise, which seems to be but a vague and uncertain inquiry; for the Mosaic description of it will not suit any place on the present globe. He mentions two rivers in its vicinity, viz. Pison and Gihon, of which no vestiges can now be found. The other two still remain, viz. the Hiddekel, supposed to be the Tigris, and the Euphrates, whose streams unite together at a considerable distance above the Persian Gulf. This gulf is eastward both of the land of Midian and the wilderness of Sinai, in one of which places Moses wrote his history. But since the formation of this earth, it has undergone great changes from earthquakes, inundations, and many other causes. The garden, however, seems to have been a peninsula, for the way or entrance into it is afterwards mentioned. We are told that a 'river went out of it;' which, according to some, should be rendered 'run on the outside of it,' and thus gave it the form of a horse-shoe; for had the Euphrates run through the middle of the garden, one half of it would have been useless to Adam, without a bridge or boat wherewith to have crossed it."

Christians, we presume, need not be told, that, however curious or amusing this inquiry may be, the determination of the point at issue is of no importance, since we are all well assured that the celestial paradise is that place of pure and refined delight in which the souls of the blessed enjoy everlasting happiness.

PARADOX, παράδοξον, in philosophy, is a proposition seemingly absurd, as being contrary to received opinions, but yet true in fact.

The vulgar and illiterate take almost every thing, even the most important, upon the authority of others, without ever examining it themselves. But although this implicit confidence is seldom attended with any bad consequences in the common affairs of life, it has nevertheless, in other things, been much abused; and in political and religious matters it has produced fatal effects. On the other hand, knowing that learned men, in order to avoid this weakness, have fallen into the contrary extreme, some of them believe every thing to be unreasonable or impossible that appears so to their first apprehension; not adverting to the narrow limits of the human understanding, and the infinite variety of objects, with their mutual operations, combinations, and affections, which may be presented to it.

It must be owned that credulity has produced more mischief in the world than incredulity ever has done, or ever will do; because the influences of the latter extend only to such as have some share of literature, or affect the reputation of knowledge. And since the human mind is not necessarily impelled, without evidence, either to belief or unbelief, but may suspend its assent to or dissent from any proposition, till after a thorough examination, it is to be wished that men of learning, especially philosophers, would not hastily, and from the first appearances, determine themselves with respect to the truth or falsehood, possibility or impossibility, of things.

A person who has made but little progress in the mathematics, though in other respects learned and judicious, would be apt to pronounce it impossible that two lines, which were nowhere two inches asunder, may continually approach towards each other, and yet never meet, though continued to infinity; and yet the truth of this proposition may be easily demonstrated. In fact, no science abounds more with paradoxes than geometry.

PARADOXI, a sort of mimes or buffoons amongst the ancients, who entertained the people with extempore effusions of drollery.

PARAGAUDÆ, amongst the Romans, were wreaths of gold, or of silk and gold, interwoven in, not sewed to, their garments.

PARAGOGUE, in *Grammar*, a figure by which a letter or syllable is added to the end of a word.

PARAGONG, a town of Northern Hindustan, in the province of Bootan. It is the capital of a district of the same name, and carries on an extensive manufacture in swords, daggers, arrows, and molten images of Buddha. The governor of the district has his residence here, dwelling in a well fortified palace, which is also a handsome building. Long. 89. 21. E. Lat. 27. 43. N.

PARAGUAY, formerly a province of the viceroyalty of Buenos Ayres, in South America, but declared an independent republic first in 1816, and again in 1826. It is bounded on the north by the province of Matto Grosso, in Brazil, from which it is separated partly by a river, and partly by a mountain ridge, its most northerly point being between the twentieth and twenty-first degrees of south latitude. The river Parana constitutes its boundary on the east, south-east, and south, with the exception of a comparatively small tract of country, called the Missions, which lies to the eastward, on the right bank of the Parana; and along the whole of the western side of the country flows the Paraguay, the confluence of which with the Parana, in latitude 27. 27. south, marks the limits of the country in this direction. In longitude it extends from 54. 40. to 58. 30. west from Greenwich, and comprehends an area of above 25,000 square miles, which is about half the superficies of England, exclusive of Wales.[1]

The history of Paraguay, from the time of its discovery until it unfurled the standard of independence, along with the other provinces, and shook itself free from European domination, presents but little except the usual story of the oppression and aggrandisement of the whites, with the fierce struggles and the ultimate submission of the Indians. But its annals since the revolution, when its destinies were intrusted to Dr Francia, one of the most remarkable men of his time, are replete with events equally interesting and instructive. According to Techo, the word Paraguay signifies the Crowned River; a name which it obtained from the Indians who inhabited the shores of the river wearing coronets made of feathers. Dr Southey, however, is of opinion that it is the same word as Paraguazu, or Great River; and this is supported by the fact, that the same word for a river is observed in the Para and the Parana. On the other hand, Azara informs us that the river and country of Paraguay derive their name from the Payaguas, who formerly inhabited that part of Brazil through which the river flows in the early part of its course, and are now the most domesticated and useful of all the Indian tribes, with the exception of the Guaranis. This name was altered a little by the Spaniards, who, substituting one letter for another, made it Paraguay instead of Payaguay. The country was discovered in 1526, by Sebastian Cabot, who was then in the service of Spain. This intrepid navigator ascended the Paraguay thirty-four leagues above its junction with the Parana, and there met an agricultural people, inhabiting the banks, but found them too fierce, warlike, and sagacious to be ensnared by promises, or induced to come to terms. After five years of fruitless attempts at negotiation, he was compelled to abandon the enterprise; and for some time the country remained almost unnoticed. In the year 1536, however, the Spaniards, after a sanguinary struggle with the natives, succeeded in forming a settlement; and in memory of the event, as well as in honour of the Virgin Mary, they called their fortified port Assumption. This was the origin of the capital city of that name, which increased so rapidly, that in eleven years afterwards it was considered as of sufficient importance to be constituted the seat or see of a bishop. The history of the country for fifty years after the first settlement presents merely a series of acts of hypocrisy and violence. The Guarani tribes, who inhabited Paraguay, and some other parts, were a brave but docile people; and though many lives were lost before the superiority of the Spanish power was acknowledged, yet, of all the tribes, the Guaranis, who were the most numerous, proved in the end the most easily and effectually reduced to obedience. But, satisfied with their subjugation, the Spaniards did little or nothing for their improvement; and it was not until towards the end of the sixteenth century that the Jesuits brought all the zeal and influence of their order to the task of civilizing the Guaranis, or, in other words, reducing them from a state of savage independence to one of civilized but complete subjugation. In the year 1586, the first settlement or mission of the Society of Jesus was formed in Guayra; and so rapidly did these settlements increase, that, in the year 1629, they amounted to twenty-one in number. These communities were of a threefold character, namely, religious, military, and manufacturing; for, whilst the Jesuits instructed the Indians in the elements of education and the truths of religion, they likewise trained them to habits of industry, and even taught them the art of self-defence. Each of the settlements was a considerable town laid out with straight streets. The houses, generally consisting of earth, where whitened, covered with tiles, and provided with verandas on either side, to preserve them from the sun and the rain. Each mission had a mother church, which was generally built of stone, and magnificently ornamented. Two curates, both Jesuits, were the only ecclesiastics who exercised parochial functions, and at the same time acted as inspectors of all civil economy.

In attempting to extend their spiritual conquest still further, the Jesuits were compelled by the Paulistas to fall back to the south of the Serra Maracaju, and concentrate their establishments between the Parana and Uruguay, in that part where these rivers approximate most closely. But at a subsequent period the Jesuits acquired an ascendency in Paraguay, as far as ecclesiastical authority was concerned; and for more than a century their influence remained unshaken. In the year 1752, when seven of the Jesuit missions were detached from Spain and annexed to Portugal, so averse were the Indians to this separation, that they had recourse to arms, and a war ensued, which is known by the name of the War of the Seven Settlements. But, after five years of hostility and bloodshed, they were entirely subdued, and their spiritual teachers, who had at first vainly urged them to submission, resumed their beneficent sway. The Jesuits, it is well known, were finally expelled from Brazil in 1760, under circumstances of unexampled cruelty; and in 1768, this was followed by their complete expulsion from Paraguay, as we learn from Cazal and the despatches of Bucarelli. During more than thirty years after this event the affairs of the country continued in a state of frightful disorder; cruelty, plunder, and misery in various forms prevailed; and the population of the Reductions, from having been upwards of 100,000, sunk to less than half that number.

With the change of masters which followed this event, the spell that bound the Indians was broken; and by the new plan of government there was established in the Guarani towns a system which in a few years led to the total ruin of the Jesuits' establishments. The successors of these missionaries appear to have been thoroughly embued with the worst spirit of religious bigotry, and to have possessed none of their redeeming qualities. Doblas, one of the administrators of the new system, and by far the most enlightened and efficient of their number, as well as the able historian of the Missions of Paraguay, strenuously urged the Spanish government to sanction such a change of management as would insure their preservation; and ultimately the king of Spain showed a disposition to adopt his suggestion. But it was then too late. The depopulation of the Missions was complete; and, in many places, the ruins of their churches and buildings are all that now remain to attest their having ever existed. The Jesuits have often been attacked and unsparingly calumniated by those who were interested in destroying the reputation of that celebrated order; but some authentic documents recently published will probably go far to correct many of the erroneous impressions which have thus been produced in disfavour of that body. It must always be kept in view, however, that, excepting the truly impartial testimony of Doblas, the records alluded to are the productions of decided partisans of the company of Jesus.[1]

---

[1] In drawing up this article we have been indebted for much valuable information to Mr W. P. Robertson, author of Letters on Paraguay, who was detained a considerable time in the country by Francia, and experienced in his own case the rigour of that suspicious despotism under which it now groans.

From the commencement of the present century until the year 1810, the country continued tranquil; but when the tocsin of revolt was sounded throughout South America and Mexico, an attempt upon the part of Buenos Ayres to supplant the governor of Paraguay led ultimately to the establishment of an independent government in that country. In the month of October 1810 the junta of Buenos Ayres despatched a thousand men under the command of Manuel Belgrano, for the purpose of vindicating their authority in Paraguay, and attaching it to the republic of the United Provinces. This army penetrated without interruption into the heart of the country, and halted within about two days' march of Assumption, the capital. In the mean while the Paraguayans collected together a force of from five to six thousand armed men, and the hostile forces came in sight of each other at the village of Paraguany. A battle ensued, in which Belgrano was defeated, and obliged to enter into a capitulation, in virtue of which he ultimately withdrew from the province. But during the conferences which took place, both before and after the capitulation, Belgrano so infected the Paraguayan officers with notions of independence, that at length these took full effect on their minds. This short but triumphant appeal to arms had given them a consciousness of the possession of strength, of which they were not previously aware; and seeing that the number of Spaniards in Paraguay was small, and being also stimulated by the example of neighbouring states, by the recollection of former wrongs, by the instinct of independence, and by the hope of gain, the principal Creoles began more and more to detach themselves from the government of Old Spain, until at last, in the course of the year 1811, they resolved to make common cause against it.

A plan for achieving independence was consequently organized, but so badly concerted, that the secret began to transpire, when some of the officers, more courageous than the rest, resolved on taking a decisive step, before detection had destroyed all their hopes. They proceeded to the residence of the governor, Señor Velasco, and having entered it, pistols in hand, arrested that functionary. So rapidly were matters arranged, that the same morning two of the chiefs of the revolution, Don Fulgencio Yegros and Don Pedro Cavallero, were united with him in the government, and a congress was called. After this body had met, the members proceeded in a regular manner to depose the governor, and supply his place by a junta, which, in imitation of that established at Buenos Ayres, professed to act in the name of Ferdinand VII. But it proceeded with much more alacrity than any similar body in the other dependencies of Spain, and did not hesitate at once to proclaim the disjunction of Paraguay from the mother country. The junta consisted of a president, two assessors, and a secretary. The person appointed to the latter office was the celebrated Don Joseph Gaspar Rodriguez de Francia, since well known by the name of the Dictator of Paraguay.

Francia, although merely secretary of the government, not only controlled and ruled it with nearly absolute sway, but with a petulance inherent in his temper, and inseparable from his impatience of contradiction or restraint. The excesses which soon followed the revolution, and which, after being long fostered in the bosom of Francia, were brought to light, year after year, as his power ripened and his jealousy matured, are too well attested by numerous and impartial witnesses to admit of dispute. He entered into office a stern and unrelenting tyrant. His fixed and unalterable resolution was to obtain power, absolute and uncontrolled; and, like other despots, he disregarded not the commission of crime in any shape, if calculated to insure his object. It was only to make his ultimate success more certain that he opened up his schemes gradually, and increased his cruelties by successive steps; and he was really the more formidable to his victims, that his sphere of action was so limited, as to bring within the ken of his quick and jealous eye every individual of the petty population of his groaning country. His colleagues in office, Yegros and Cavallero, were men of mean capacity; and whilst they were exhausting in parade the pleasure of newly-attained power, the man destined to become dictator of Paraguay was planning, in secret, those designs which not only overthrew all competitors for office, and deposed his partners in the government, but left him the sole possessor of that iron sceptre with which he has ruled his people, and overthrown every presumptuous aspirant after liberty. From the moment of his attaining the rank of consul, he paid the closest attention to business. His first care was to organize a body of men called *Quarteleros*, from being shut up within the only barrack, or *quartel*, in the town. He also organized a body of militia for the defence of the country against external invasion. He pulled down the monastic institutions, because he knew well the influence of the priests over his bigoted countrymen; and influence, in his estimate of it, was crime. Every man of education was turned out of the civil department, and replaced by low-born and uneducated tools of the dictator. The Inquisition was abolished, because it carried the semblance of an *imperium in imperio*. No holy processions, no night services in the churches, were permitted, because Francia deemed none so likely to foster treason, or to arm the hand of the assassin against the enemy of the church. At length he entirely threw aside the mask which had hitherto imperfectly concealed the real ferocity of his disposition. Whilst he was yet consul, and only dictator *pro tempore*, he had contented himself with immuring his victims in prisons, from which he in no instance released them; but now not only were the jails insufficient to contain the unhappy objects of his suspicion, but the scaffold began to stream with blood, and to afford him an easier and quicker mode of ridding himself of every one whom he chose to consider as a political culprit. Vague and remote conjecture, the villanous tales of informers, nay, even an inauspiciously-interpreted look or action, entailed banishment or death upon the suspected or denounced individual. He founded a settlement, to which he gave the name of Tevego; and thither he banished, upon the most trivial pretext, or slightest suspicion, all his least formidable enemies. This place, which forms the Botany Bay of Paraguay, is 120 leagues above Assumption; except Bourbon, it is the most northerly point of that country; and being situated on a marsh, it is not only a hot-bed of malaria and mosquitos, but destitute of every thing capable of rendering existence tolerable. The original object of selecting such a spot for banishment was that of gratifying absolute cruelty of disposition; the collateral one, that of establishing a colony of outcasts sufficient to resist the incursions of the indomitable and ferocious tribe of the Mbayà Indians. The unsettled state of the neighbouring provinces caused many of their inhabitants to seek refuge in Paraguay; but the dictator, ever jealous of new-comers, sent most of them to languish as exiles in Villa Real and Tevego.

---

[1] These religionists, who acted as missionaries in Paraguay, were certainly not so bad as their enemies represented them, and yet by no means so philanthropic and disinterested as their friends have described them. Aggrandisement for themselves, and complete dependence upon the part of the Indians, were the undeviating principles of their government. Uniform and constant labour was exacted from their subjects on the one hand; and a humane, mild, paternal, and wise rule was exercised in return; in fact, the chains of the Indians sat so lightly upon them as to be wholly imperceptible to their simple and guileless minds.

The dictator, proceeding on his worse than Chinese principles of excluding intercourse with all foreign states, laid prostrate the commerce of the country; and having thus crushed the energies, and cut off the resources, of thousands of his countrymen, he found it necessary to turn their attention to agriculture, and the manufacture of cloth from the native cotton of the country. This was pretty much as if the Tartar sovereign of China should prohibit the manufacture and exportation of *tea*, and set his subjects on the exclusive cultivation of rice and cotton for their own consumption. Less scrupulous than the head of the Celestial Empire, Francia did what the other has never attempted. He said, You shall have no intercourse with foreign countries; let the growth of the Paraguay tea, the cultivation of the Paraguay tobacco, the interminable forests which furnish timber, and the sugar-cane plantations which enrich your estates, be disregarded; and every man of you turn his attention towards deriving his means of subsistence from his own lands, and his means of clothing from his own looms. The merchant who had before made L.500 a year by the exportation of his commodities, was now ground down to L.50 at most, derivable from the cultivation of his estate. Ships rotted upon the beach; produce mouldered to decay in the warehouses; the inhabitant of a spacious house was reduced to a mud cottage; and this system Francia called an encouragement of agriculture. Having destroyed the spirit of the country, Francia now succeeded in laying prostrate its natural resources. Attempts were from time to time made to bring down the haughty authority of this despotic chief; but they were all in vain. Every conspiracy was detected, and every such detection conducted more numerous victims to the gallows, chains, dungeons, imprisonment, or banishment to Tevego. The towns of the whole country were placed under the most rigid discipline; every inhabitant of every house felt as if his father, brother, or wife, might be a spy; the whole land groaned and lay in abasement, under a trembling awe of its relentless governor. Bonpland, the enterprising companion of Humboldt, was detained nine years a prisoner, because he had dared to form an establishment for the manufacture and exportation of tea; and he was released at the end of that term, not from any latent spark of humanity on the part of the dictator, but because he had acquired not only great popularity in that part of the country where he was fixed, but a considerable property, of the whole of which he was stripped, when thrust forth at a moment's notice from his home. He was allowed to take with him barely as much as sufficed to carry him to Buenos Ayres. He only left Paraguay in the year 1831. The British subjects who had been detained by the arbitrary will of the dictator were released some years previously, by a happy interference on the part of Sir Woodbine Parish, then (1826) consul-general of Buenos Ayres. Francia's great desire was to establish a direct diplomatic intercourse with England, and he fancied that by releasing his *detenus* he would accomplish his purpose. In this he was mistaken; and upon finding himself afterwards disappointed, he gave vent to an ungovernable fit of rage.

Paraguay, with the exception of the part which faces the north, appears to be wholly enclosed by the rivers Parana and Paraguay; and these noble streams constitute the most remarkable physical features of the country. There are, besides, a great number of smaller currents of water, affluents of the large rivers, which traverse the country from east to west and from west to east, falling respectively into the Paraguay and the Parana. The country is thus abundantly supplied with water for the purposes of agriculture; and, with regard to navigation and commerce, the breadth and depth of the two great rivers by which it is nearly surrounded place it almost on an equality with an island of the ocean. Generally speaking, the face of the country is level; and, though sometimes undulating, and here and there studded with hills, it is destitute of any mountain ranges, notwithstanding that, upon most maps, a cordillera, apparently of great extent, is made to traverse the country, having a general bearing from north to south. These elevations, which are situated considerably nearer the Parana than the Paraguay, are not deserving of the name of mountains. The rocks chiefly found in the country are arenaceous, not calcareous, and they vary in hardness and in grain. There are here no mines of the precious metals, and the minerals which belong to it do not so materially differ from those found in many parts of the United Provinces of the Rio de la Plata as to require specific mention. There are no salt marshes or brooks of any size, such as are common in this region of America; but a substitute for them is found in the earth called barrero, which consists of a mixture of clay and salt. This is devoured with such avidity by all animals, that they cannot be driven from it by blows, and have been known to die in consequence of swallowing too much of it. Salt is obtained in Paraguay by collecting the white efflorescence which is found in some valleys during the dry season. This is dissolved, filtered, and subjected to evaporation, when the crystals of salt are formed; but the quantity produced is so small that Paraguay is dependent on Buenos Ayres for supplies of this necessary article. The soil of Paraguay is invariably fertile, and of the same quality throughout.

The climate, although hot compared with that of Great Britain, is highly salubrious. Azara, whose account of the country, although half a century old, is still the best which we have, found the heat throughout the summer to average 85° of Fahrenheit at Assumption, the capital. This was in his chamber; but on very warm days the thermometer stood at 100°. In winter it descended to 45°, which may be taken as the medium temperature of this season; but Azara says, that, in extraordinary seasons, he found water congealed in the court of the house which he occupied, although this statement has been questioned. It is generally observed in the country, that it is always cold when the wind blows from the south or from the south-east, and warm when it blows from the north. In fact, the heat and the cold seem to depend much more on the winds than on the situation or the declination of the sun. The most common winds, and these invariably hot ones, blow from the east and the north. Those from the south and south-west are much less frequent, though invariably cool and refreshing. A west wind is scarcely known. The climate is moist; and a considerable quantity of rain falls during the summer months (which in this quarter of the globe correspond to those of our winter), accompanied by terrible storms of thunder and lightning.

In the abundance and variety of its vegetable productions, Paraguay equals the most prolific portions of South America; and in one tree, that which supplies the celebrated *maté*, it stands unrivalled. Not that it is solely confined to this country, for it is found more or less over the whole table-land; but it is produced there in the highest perfection, and in the greatest quantities. The *yerbamaté* grows to a goodly size, and is cut to supply the market in every state, from that of a shrub to that of a full-grown tree. It resembles the tea-plant of China, and being in fact a species of wild tea, it is commonly known in commerce by the name of "Paraguay tea." The leaves and thin stalks are cut off every two or three years, that period being necessary for its reproduction. The small branches, when gathered, are dried by means of fire; the leaves are then roasted and partially bruised, after which they are packed up in hides, and sent to the different markets of South America. This leaf constitutes the principal article of export from Paraguay. The beverage which is produced from it by infusion has a bitter flavour, not unlike Bohea; and in some parts of the continent the use of it is said to have prevailed amongst the Indians from time immemorial.

Every variety of wood is extremely abundant in Paraguay; the territory of this republic being in fact as remarkable for the extent and excellence of its forests, as that of Buenos Ayres is for the total want of them. The vessels which are built here are extremely durable. Some species of the wood of Paraguay are so hard as to resist the best tempered axe. The hapacho, especially, is a wood of the hardest and most durable kind, equal, if not superior, to the best of our oak. Of the hapacho, vessels are built which live on the waters for fifty years, and rafters are made which support the roofs of houses for double that time. So hard and close is the grain of this wood, that no worm can penetrate it, and no rot can ever assail it. The carts of Buenos Ayres are made of this or similar woods; the algarrobo, the urundey-pita, and the urundey-iray, being amongst the strongest. The last, being very handsome, is likewise used for furniture; and when polished, it is equal in beauty to rosewood, but of a lighter colour. The other trees the timber of which is in general use are, timbo, and the tatayiba or wild mulberry; lance-wood, and the orange tree, of which gun-stocks and parts of carriages are made; carandey, a large palm-tree, yielding a very hard wood; the tatare, strong, and much used in the construction of vessels and machinery, as is also the yberaro; with the cedar and others. There is a tree found here which grows in a very singular manner, the trunk being composed of several stems closely twined round one another, thus forming to appearance one solid mass. The bark of the cebil and curupahi, found in Paraguay and Corrientes, is used for tanning. There are also several trees and plants which the natives make use of for dyeing their linen. A large tree called palo santo, or holy wood, produces an odoriferous gum, which is extracted by boiling pieces of the wood, and is used as a perfume. The incense tree, so called from the gum which it produces, is used in the churches as incense. The mangaysy produces gum elastic, of which a very durable sort of match is made. There are many other trees in the country which yield different kinds of gum, and some are reputed to possess great medicinal powers. With these a Jesuit made numerous experiments upon the Indians, during a residence of forty years amongst them; and having himself lived to the age of a hundred and twelve years, his medical aphorisms were held in high veneration. Rhubarb jalap is amongst the numerous medicinal plants which grow in Paraguay. The cordage used in the vessels is mostly made from the fibres of plants which are found in the country. Tobacco, coffee, sugar, and cotton, are all cultivated here; and maize grows to great perfection, being much used as an article of diet. Rice, indigo, cotton, and the vine, which thrives but indifferently, are also cultivated to a great extent. A root called aipim or pompin is sometimes made use of as a substitute for bread. Honey and wax, vegetables, and tropical fruits of various kinds, are abundant. Indeed Paraguay has always been held in the highest estimation for the abundance, variety, and value of its productions. The animal kingdom is as extensive and various as the vegetable. Most of the animals belonging to this part of South America are found in Paraguay; amongst which may be mentioned the cougars, jaguars, tapirs, and the water-wolf. The feathered tribes in particular have long been celebrated for their number and their beauty; including the ostrich, parrot, vulture, turkey, humming-bird, duck, and other game. Boas, rattle-snakes, lizards, and other animals, are plentiful; and ants, locusts, and other insects, are numerous and troublesome, sometimes very destructive. Immense herds of cattle roam in the vast plains of Paraguay, and their hides and tallow constitute considerable articles of export.

The inhabitants of this country are now almost wholly engaged in agricultural operations, a portion only giving such attention to manufactures as the wants of the whole demand. Before the non-intercourse system of Francia was introduced, the population of the country was chiefly employed on articles of export; the yerba-maté, tobacco, lumber of every kind, sugar, rum, tanned hides, &c. But when, under Francia's rule, these became useless as exports, his own policy, as well as the natural wants of the people, turned the industry of the labouring masses into new channels. The importation of cotton was superseded by the great additional growth of the native plant. Rice, maize, the yucca root, and various leguminous and succulent plants, shared an equal cultivation with the sugar-cane. The breeding of horses and of cattle was enjoined and encouraged; and Francia's whole power was employed to realize his boast, that he would make the people dependent on themselves, and not on foreigners.

Such have been a few of the results of the anti-social policy of Dr Francia. He has changed the richest and most commercial province in the old viceroyalty, Buenos Ayres excepted, into perhaps the poorest, notwithstanding the prodigal hand with which nature has scattered over the country her most luxuriant productions. He has arrested the progress of civilization, and forced the inhabitants of Paraguay to retrograde towards barbarism. He has demoralized an active, hospitable, open-hearted, and simple-minded people, and converted them into a ferocious soldiery or a mass of spies on the one hand, and a terror-striken, slavish multitude, on the other. And to these miserable results he has waded through the blood of innumerable victims, who have either perished on the scaffold, or sunk to the grave in the noisome dungeon and the pestilential swamp, where a slower but not less certain death awaited them.

Before the reign of Francia commenced, the trade of Paraguay with her neighbouring provinces, and particularly with Buenos Ayres, was very considerable. About eighty square-rigged vessels were constantly employed in the trade, besides a great number of river craft, under the names of garandumbas, piraguas, balsas, and chalanas. The exports consisted of about 40,000 bales, containing 8,000,000 lbs. of yerba-maté, 7000 to 8000 petacones of tobacco, containing 1,000,000 lbs.; and these two articles produced about one million two hundred thousand dollars annually; whilst lumber, rum, sugar, tanned hides, and a variety of minor articles, produced about half a million more.

Before Francia assumed the reins of government, the Paraguayans never thought of extending their care to the cultivation of any other article than the tobacco-leaf, the sugar-cane, cotton, and the yucca-root. Maté, which grows without any aid from art, in the vast forests of the north and east, engaged almost all hands. Melons, oranges, Indian corn, and other fruits, together with rice, maize, and the two sorts of yucca-root, were now cultivated upon a more extended scale, and with much greater diligence; and vegetables, which were hitherto unknown in Paraguay, now cover the plains. During 1819, that destructive insect the locust, which visits Paraguay every five or six years in such multitudes as even to obscure the sun, spread devastation over a circumference of more than eighty leagues of country. A scarcity seemed inevitable, for the preceding harvest had been unusually bad; but, to prevent this calamity, the dictator ordered the farmers to sow, a second time, a considerable portion of the land which had been laid waste. The experiment was completely successful, and the second harvest proved one of the most abundant that had ever been known. The proprietors had never before dreamed of reaping a double crop in one year. Artisans also sprung up under the auspices of the despot; and out of rude blacksmiths, shoemakers, and masons, he contrived, by an indefatigable, and in many cases personal superintendence, to create a double number of expert whitesmiths, saddlers, and architects. Of the amount of the trade of Paraguay no data from which to form an estimate have been obtained. The two great resources of the country are the forests of timber for building, and the herb of Paraguay; and these form the staple articles of export. But, besides, there are still sent out of the country tobacco, sugar, cotton, sweetmeats, tapioca, rum, wax, tallow, and hides. The imports are not numerous; for it has been the constant aim of the dictator to render his country, if possible, altogether independent of any other.

It must be very evident, from what has been said, that the whole power of government is centred in the dictator. There are, indeed, in imitation of the Spanish system, a minister of finance, a secretary of state assisted by an under secretary, and a remnant of the ancient cabildo, consisting of two alcaldes, stationed at Assumption; conciliators, and commissioners of police, together with a "faithful executioner," an inspector of markets, weights, measures, and some others; and, lastly, "an advocate of minors," whose duty it is to watch over the interests of minors and of slaves. But the highest of these officers is little better than a head clerk, who merely acts under the orders of the dictator. The republic is divided, as in former times, into twenty sections or *comandancias*, four of which have for their capitals respectively the towns of Neembucu or Villa del Pilar, Villa Rica, Yquamandiu or Villa de San Pedro, and Villa Real de la Concepcion; the only towns in the whole country, besides Assumption, which is distinguished by the name of *ciudad*, the Spanish for city, the others being called villas. But since the suppression of their cabildos, which were charged with the local administration of justice, these towns no longer enjoy any exclusive privileges. Each section is under the authority of a commandant, who executes the orders of the dictator, directs the operations of the police, decides on minor offences, and exercises the functions of conciliator. He has under his orders some inferior officers of police; and there is also in each section a receiver of taxes. The laws by which Paraguay ought to be governed are those made in the time of the Spaniards; but they have been so altered, first by the junta, and subsequently by the dictator, that the will of the latter may be said to be the law of the country. Justice is administered in civil cases by the parties appearing before the commandant or one of the alcaldes, according as the place of trial is in the capital or in the country, and by their pleading their cause in person. This appears to be a court of conciliation similar to that which is established in Norway. If the attempt at adjustment prove unsuccessful, the cause goes in the first instance before one of the alcaldes, who pronounces a judgment, from which the parties have the right of appeal to the dictator. In criminal cases he is generally the judge himself; and he always proceeds in a summary manner. With regard to punishments we can only speak generally. They are severe, death being the award of crimes which in Great Britain would only be visited by a few weeks' confinement; and execution is made to follow the sentence as quickly and surely as the thunder-peal follows the flash of lightning. There are two kinds of prisons, namely, the public prison and the state prison, and both are kept in a wretched condition. The prisoners are treated with the utmost severity, and attempts to escape from these horrid places of confinement are punished by death. The police is exercised in Paraguay by all those in office, from the dictator down to the lowest functionaries, called zeladores. All the officers of government, including a train of spies, and also the regular troops and the militia, constitute one great body of police, which exercises a surveillance much stricter than that of France under Fouché. Passports are not only necessary to a person who wishes to quit the country, but also before he can travel twenty leagues from his residence. The whole population is thus kept in a sort of captivity. The post-office is also strictly looked after; and indeed the system of police is a source not only of great annoyance, but often of great loss, to the inhabitants. There is kept up a regular army of about 3000 men; and the body of militia, which is entirely under the orders of the dictator, is 10,000 strong. Every native of Paraguay must enter the service as a private soldier, and learn the military exercises; and with regard to the militia, the name of every free man in the republic who has arrived at the age of seventeen, and is capable of bearing arms, is inserted in the rolls. There is, besides, a troop of artillery, and a small naval force.

The revenues of the state arise from tithes, a tax upon shops and storehouses in the capital, an import and export duty, the sale-duty, stamps, postage of letters, fines, confiscations, "droits d'aubaine," and the produce of the national domains. The tithes are the most productive source of the public revenue; they are levied upon all species of agricultural produce, upon flocks and herds, and even upon poultry. The import and export duties can be received only at the custom-house at Assumption, and both are very heavy. The duty upon all sorts of goods brought into the country is nineteen per cent. *ad valorem;* but the duty is calculated on the retail price, and there is an additional impost of four per cent. as sale-duty, so that the import-duty cannot be less than thirty per cent. The sale-duty is levied upon every thing that changes owners, except agricultural produce, and even for this there is a charge made at Assumption. On articles exported the duty levied is nine per cent. *ad valorem.* The other branches of the revenue, such as the stamp-duty and the tax upon letters, yield annually a considerable sum. The national domains of Paraguay extend over almost the half of its territory, consisting of pasturage-lands and forests, the Jesuit Missions, the possessions of other religious corporations, and a great number of country houses and farming establishments confiscated by the dictator. The revenue must therefore be very considerable; but of its actual amount no one except the dictator has any idea.

When Dr Francia assumed the reins of government, he placed himself at the head of the church as well as of the state. The bishop, who opposed the revolution, was superseded by his vicar-general, Pay Montiel, a creature of the dictator's. Religious corporations were suppressed, and the clergy were secularized, chiefly by reason of the dictator's inextinguishable hatred of all institutions which bore any semblance of independence. In short, from the contempt in which he held the monks, he did every thing in his power to throw ridicule upon the monastic order. In Paraguay, as well as in the rest of South America, the education of youth was formerly intrusted exclusively to the monks, who established schools in the convents. Subsequently elementary schools, taught by lay masters, were established in all the districts, and a college of theology was founded at Assumption. The latter was suppressed by the dictator in 1822; but he allowed the elementary schools to remain, without, however, taking any steps to improve them. But as no obstacles were thrown in the way of establishing private seminaries, several of these have been opened in the capital, and education is rather on the advance. With regard to literature, in the ordinary acceptation of that term, it may be said to be wholly unknown in Paraguay. In 1827 there was not a printing-press in the country; but since then, this instrument of civilization in a free country, and of oppression in an enslaved one, has been established, and of course exclusively used by the dictator.

The population of Paraguay has been variously estimated, by those who have visited the country, at from 300,000 to 500,000 souls; but the Weimar Almanac for 1835, without giving any authority, states the number as high as 600,000. The great mass of the inhabitants are Creoles; the Indians composing about one tenth, and the mixed race and the black about two tenths, of the whole population. The natives of Paraguay are gifted with considerable natural talents, and are of a mild, hospitable, and generous disposition, but careless, unsteady, and as easily swayed to evil as prompted to good. In regard to morals, their minds may be said to hang in even balance between virtue and vice, and readily to take an inclination either way. Hence the remarkable influence which the Jesuits had over them; hence also the scenes of anarchy and bloodshed which followed their expulsion; and hence, lastly, the secret of Dr Francia's system of despotism. Although not possessed of the ardour of the inhabitants of the torrid zone, they support the greatest fatigue with courage and perseverance; but at other times they will remain whole months in a state of the most complete inaction. They are proud of their ancestors, as having been the founders of the first establishment formed in South America, and they have always been distinguished from the other Creoles by their national spirit. In Paraguay the conquerors have adopted the language of the conquered, and very many of the Creoles are perfectly ignorant of Spanish, particularly the female part of the rural population. In the mixed races of Indian and black, the child follows the condition of the mother, and is free or servile accordingly. Although the men of colour are in a great measure free, yet they have always been supposed to be unfit for office; and notwithstanding that, since the revolution, some of them have been admitted to places of trust, the ancient Spanish prejudice is not the less strong against them. The blacks are very few in number.

That part of Paraguay which is known under the name of the Missions is governed in a somewhat different manner from the rest of the country. It extends over a surface of 600 square leagues, on the right bank of the Parana, to the south-east of Assumption. The population consists of eight tribes of Indians, and some thousands of whites, who obtained land from the government, and established themselves there, after the expulsion of the Jesuits. The white population is governed by the commandants, as in the other parts of the country; but the Indians attached to the soil, and condemned to work on the state lands, have peculiar officers, who, under the name of administrators, manage these lands, besides exercising the functions of commandants. These two classes of functionaries are under a lieutenant of the government, who has the chief command of all the country of the Missions, but without any control over matters of finance. Several other villages inhabited by Indians in the interior of the country, and which formerly belonged to the Jesuits or other religious communities, have also managers set over them, and are subjected to the authority of the commandant in whose section they happen to be situated. The condition of the Guarani Indians, who are still in the Missions, is inferior to that of the slaves. In the time of the Jesuits, the Guaranis were tolerably well fed and partially clothed; and the fathers, by allowing them processions, dancing, and music, upon holidays, contrived to reconcile them to a state of dependence, and ameliorated their condition whilst they profited by their labour. But after the expulsion of the Jesuits, the managers who succeeded them were chiefly occupied in pillaging the settlements, overworking the Indians, and rendering their fate still more wretched by the utter destitution in which they were held. Since the year 1823, however, the power of the managers has been contracted by the dictator, and neither purchases nor sales have been allowed to be made without his permission. He also employed the Indians in the service of the government.

Assumption, the capital city of the republic of Paraguay, is built in the form of an amphitheatre, on a rising ground, on the left bank of the river Paraguay, in latitude 25. 17. 15. south, and longitude 58. 5. west from Greenwich. It has been so completely altered by the dictator, that little of the ancient city remains. But the idea of rebuilding it in a more regular manner occurred to him in the year 1820, upon the discovery of a conspiracy against his life. Its streets were crooked, irregular, and the greater number of them so narrow as to deserve only the name of lanes. The houses, consisting only of one floor, generally stood apart from each other, and being interspersed with trees, little gardens, brushwood, and patches of verdure, they presented the aspect of a village rather than that of a city. Numerous springs issued from the ground in every part of the town, and formed streams, or stagnated into pools; whilst the rain furrowed and cut up almost all the sloping streets. The dictator commenced his architectural reformations by tracing out, in the least populous parts of the city, longitudinal streets, from north-west to south-east, crossed by others at right angles, all of which were ordered to be made from thirty-five to forty feet in width. These new streets served him as a model for the others which were to be opened throughout the city. They were distant from each other one hundred paces; but whenever a public building interfered, the space was either diminished or augmented, in order to leave it standing. The proprietors of houses which interfered with the new line of street were ordered to demolish them; other buildings were pulled down by the mandate of the dictator, and their materials employed in levelling the ground. In short, he completely destroyed the old city; and as he had only to issue his commands to insure obedience, a new one soon rose in its stead. The owners of the dwellings which were thus demolished were not indemnified for their loss, and many rich proprietors were compelled to build mansions on sites pointed out to them. The dictator paid only the master workmen, whose plans were executed by some hundreds of prisoners. The various divisions of the country were obliged to supply all the materials gratuitously; and if the buildings carrying on were outside the capital, the owners of them were also bound to furnish a certain number of workmen. It was in this manner that the fortresses on the frontiers, and several barracks and other edifices at Neembucu, at Assumption, and at Villa Real, were constructed. New roads were also opened through the woods, and others which had been broken up by the rains were widened and repaired. Forty houses were built and let for the benefit of the state; and at every step in the progress of these operations the country people were called upon either for their personal services or for the use of their cattle. The result has been a perfectly renovated city, containing a number of spacious public buildings, large streets, and handsome private mansions. Assumption is the seat of government and the residence of the dictator; and here are all the different offices for the transaction of public business. The number of inhabitants may be estimated at 12,000.

Paraguay, a great river of South America, which forms the western boundary of the republic just described. Its head waters are formed by a great number of streams which rise in those mountainous ridges called Sierra del Pary, or Paraguay, a portion of the extensive Paricis, situated in the Brazilian province of Matto Grosso, in latitude 13. 30. south. A little below the last of a series of seven lakes, called the Sete Lagoas, which communicate with each other by narrow outlets, the Paraguay flows for a short distance through a swampy country in a northerly direction; it then winds round by the west, and takes a southerly course, which it maintains to its confluence with the river Parana, at the south-western extremity of Paraguay. The first large stream that joins it is the Xauru, which originates in the campos of the Serra Paricis, and after flowing a long way southward, bends to the east-south-east, and falls into the Paraguay in latitude 16. 25. Father Quiroga informs us, that, below the Xauru, the Paraguay separates into two considerable branches, the principal one running in a narrow but deep channel through the Xarayes, and the other branch flowing some leagues to the westward. The Xarayes is an immense lake formed by the abundant rains which fall during the months of November, December, January, and February. At this season the streams and rivers which feed the Paraguay become prodigiously swelled; and the latter river, unable to continue in its legitimate channel, inundates the country for many leagues on both sides. A great part of the beds of the St Lourenço, Tacoary, and Mondego, and other tributaries on the eastern side, as well as the small lakes on the western side, which appear to remain permanently, become portions of this periodical Caspian; and the elevated lands assume the appearance of islands, inhabited by an accumulation of birds and wild beasts. Whilst the floods continue, it is customary to navigate over the plains where the current is less rapid, traversing prodigious plantations of rice annually reproduced by nature without any human assistance, or sustaining any damage from the waters, because it grows as they increase, always presenting, besides the ear, a considerable portion of the stalk above the flood. As the quantity of rain which falls is much greater in some years than in others, the size of the Xarayes varies accordingly; and as its figure or contour depends on the nature of the country over which it spreads, it is also extremely irregular, and cannot be accurately described. Azara, who is always to be depended upon, thus speaks of this great lake. "It commences before the seventeenth degree of latitude, and it may have in this place twenty leagues of breadth to the east of the river Paraguay. It preserves nearly the same size until the twenty-second degree, that is to say, during more than one hundred leagues, without speaking of the Sugar Loaf, Pau-de-Azucar, and other little mountains which it surrounds with its waters. To the west of the same river the lake commences at 16. 30. and continues to 17. 30., immersing many leagues of the province of Chiquitos. From 17. 30. to 19. 30. its extent is inconsiderable; but afterwards, to the twenty-third degree, it continues to extend much in the Chaco, and still more in the country of the Chiquitos. We may, by approximation, estimate its length at one hundred and ten leagues, and its breadth at forty." During a great part of the year it remains perfectly dry, and covered with the corn-flag and other aquatic plants. There are several other lakes of the Paraguay, of much the same nature as the Xarayes, such as that of Aguaracaty, about the twenty-fifth degree of latitude; those which are found to the north and south of the lake Ypoa, situated under the twenty-sixth parallel; those of Neembucu, under the twenty-seventh; and a multitude of others, situated on the eastern margin of the Paraguay, and on all the streams which flow into it.

The affluents of this great river are very numerous. The Porrudas, or St Lourenço, joins it in latitude 17. 52., some writers say nearly a degree farther south; and the Tacoary, in latitude 19. 15., in front of a square mass of an elevated range, called Serra Albuquerque. Still further south are the mouths of the Mondego, thirty-five miles below which are two high mounts, fronting each other, upon the banks of the Paraguay. On the western mount is built Fort Coimbra. The Tepoti flows into the great river, in latitude 21. 45.; and this is nearly the limit between what is called the High and the Low Paraguay. The following is the order in which the rivers fall in, according to Father Quiroga, who navigated the Paraguay from the mouth of the Xauru to the confluence of the Parana. The embouchure of the Corrientes is in latitude 22. 2.; that of the Guarambari, in 23. 8.; that of the Ipaneguazu, in 23. 28.; that of the Ipanimini, in 24. 4.; that of the Xexui, in 24. 7.; that of the Quarepoti, in 24. 23.; that of the Ibobi, in 24. 29.; that of the Mboicaé, in 24. 56.; and that of the Salado, in 25. 1. A little below the city of Assumption, the Pilcomayo runs into the Paraguay by three mouths, after a very long course, its origin being amongst the mountain ridges where the city of Potosi is situated. The mouth of the Tebiquari is in 26. 35. The Bermijo, sometimes denominated the Rio Grande, joins in latitude 26. 54., eleven leagues of direct distance from the city of Corrientes, where the magnificent junction of the Parana and Paraguay takes place, in latitude 27. 27. and longitude 58. 22. west of Greenwich. The combined rivers bear the name of Parana till the confluence of the Uruguay, when all these appellations are sunk in that of the Rio de la Plata. The Spaniards, however, sometimes call the river by the latter name as far up as the junction of the Pilcomayo. Of these tributaries of the Paraguay, by far the largest and most important are the rivers Pilcomayo and the Bermijo. They offer great advantages to a commercial people; but, from the scanty population of the country through which the greater part of their course lies, these have not been turned to proper account. Both rise in Bolivia, the first, as has been mentioned, near the city of Potosi, and the second in the vicinity of Tarija. They descend at first with considerable velocity from the heights where they originate; but after they reach the level country, they flow in a tranquil and majestic current. According to the best information, they possess no inconvenience except their numerous windings, which arise from the want of fall in the ground of the Gran Chaco, through which they run, and which is the most level tract of country in all South America.

The Paraguay is navigable for vessels of a hundred to a hundred and thirty tons, provided they do not draw more than ten or at most eleven feet of water. One ship, indeed, of three hundred tons burthen, called the Primera, was built at Villa Real, and floated down the stream to the ocean. To obtain correct ideas of the breadth and depth of the Paraguay, Azara measured it at a time when it was lower than it had ever been known to fall in the memory of man. The breadth in several parts was found to be 1332 French feet; and from soundings made to ascertain its depth, and experiments to prove the velocity of its current, Azara calculated that it discharged, when at the very lowest, 98,303 cubic toises of water per hour. The mean quantity, he supposed, would be double this at least, if not more; so that, according to his estimate, the Paraguay discharges throughout the year, at the city of Assumption, nearly two hundred thousand cubic toises of water per hour. So little does the country slope in this part of the South American continent, that it has been calculated that the Paraguay in its course from north to south does not fall above one foot between the eighteenth and twenty-second degrees of latitude. At the capital the waters of the Paraguay are always clear; for the rains which fall either above or below that city are not sufficient to trouble so large a stream. The periodical increase of the river commences at Assumption in the end of February, and the augmentation continues with admirable equality till the end of June. It then begins to decrease in the same regular manner, and this continues during an equal space of time. This periodical increase is much greater in some years than in others; and at Assumption the waters sometimes rise five or six toises above their ordinary level, thus inundating a great part of the country; yet there is little variation at the commencement or at the end. This increase of the river, which, singularly enough, does not begin till the rains have ended, appears to be thus produced. All the rain which falls is first collected in the great natural reservoir Xarayes; and it is not until this is full to overflowing that it discharges itself into the river Paraguay. We find that the Parana, which has no basin of this description to collect the periodical rains, is at its greatest height in December, about a month after the rainy season has set in; so that by this singularly happy arrangement, the rivers Parana and Plata are kept during a great part of the year at a very considerable size. (R. R. R.)

PARAIBA, or Parahyba, a province of Brazil, in South America, bounded on the south by Pernambuco, on the north by Rio Grande da Norte, on the west by Sera, and on the east by the Atlantic Ocean. It comprehends about two thirds of the old captaincy of Itamarca, and has between eighteen and nineteen leagues of sea-coast, whilst towards the interior it extends westward about sixty leagues. It derives its name from the river Paraiba or Parahyba, which, originating in the Serra da Jabitica, in Cayriris Velhos, not far from the source of the Capibaribe, runs to the north-east, and discharges itself into the Atlantic by two mouths on either side of the island of St Beneto. Its principal tributary is the Paraibuna, which flows down from the back of the Serra da Montequeira, under the name of the Rio Preto, which is a mere translation of the Indian name for the river. It is about fifty yards in breadth at the junction, flowing with a rapid and turbid current, over a sandy channel eminently auriferous. Caldcleugh informs us that the current of the Paraiba is also very rapid, being about seven miles in the hour, and the water cool, being twelve degrees under the temperature of the air. "The road was excessively bad, being extremely narrow, with a gulley down the centre; and the soil being a red clay, was very insecure, from the humidity. From the summit the views on all sides were magnificent; but more particularly the one which extended along the valley of the Paraiba. Here and there the eye caught a glimpse of the river glistening amidst the deepest and most luxuriant vegetation." This description does not agree with the account sometimes given of Paraiba, that two thirds of the whole surface are incapable of any kind of culture. Mr Southey justly characterizes this statement as very erroneous; and recent travellers confirm the fact, that a great part of it possesses a prolific soil, and an agreeable although hot climate. The surface of the country, however, is very uneven, elevated ridges traversing it in various directions. Mr Koster travelled to Paraiba from Recife, by way of Goiana. The road between Goiana and Paraiba, a distance of thirteen leagues, presents nothing particularly interesting. The hills are steep, but not high; the principal objects are woods, plantations, and cottages. Returning by the sea-coast, he found a considerable portion of it uninhabited; but wherever the land was low, and the surf not violent, cottages were seen, and the banks of the rivers were partially settled. When the action of the tide ceases, the streams all become insignificant, and most of them quite dry. Nearly the whole of Brazil is celebrated for its vegetable productions, particularly timber; and Paraiba is not deficient in this respect. It is noted for the excellence of its Brazil wood, and its sugar, the culture of which, however, has much declined, on account of the droughts which are frequently experienced here; and cotton has taken its place, that plant being said to endure a want of water better than the cane. In the year 1820 a few Britons established themselves here, in connection with some merchants at Pernambuco, for the purpose of reviving and extending the trade. The exports of sugar at one time exceeded nine hundred chests annually, but in 1819 it had sunk to less than half that quantity; whilst in the same period the cultivation of cotton had increased in proportion as the cane had decreased.

Paraiba, the capital of the province, is situated on the south bank of the river Paraiba, about ten miles from the sea, the river being navigable for a considerable way above the town. The port is capacious and secure, and defended by two or three forts. Vessels of one hundred and fifty tons can pass the bar; sumacas can ascend to the capital, and canoes as far as the town of Pilar, which is situated about forty miles higher up. When this captaincy was taken possession of by the Dutch in 1634, it contained only seven hundred families and twenty engenhos. They changed the name of the capital to Ferdinand, in honour of the Prince of Orange; and gave a sugar loaf for its arms, in allusion to the great quantity of sugar obtained from the district, and in conformity to a plan then adopted for granting armorial bearings significant of the principal leading articles in the different captaincies under their dominion. The principal street is broad and well paved; the houses are mostly of one story, but some of the buildings are described as handsome. There are several large and respectable convents here, but of late years they have fallen into decay. Indeed the same thing may also be said of the city, for much of the commerce which it once enjoyed is now centred in Recife, a seaport in Pernambuco. The lower town, which consists of small houses, is situated, Mr Koster states, upon the borders of a spacious basin or lake, formed by the junction of three rivers, which discharge their waters into the sea by one considerable stream. These rivers are probably the Paraiba and its two confluents the Guarahu and the small river Unhaby. "The banks of the basin," he adds, "are covered with mangroves, as in all the salt-water rivers of this country; and they are so close and thick that there seems no outlet. I did not follow the river down to the sea, but I understand that there are in it some fine islands, with good land, quite uncultivated." One of these has since been cleared, and some salt-works erected upon it. Paraiba lies out of the road from the sertam to Recife; that is, out of the direct way from the towns upon the coast farther north; the inhabitants of the interior will therefore, in preference to Paraiba, make for Recife, as the more extensive market for their produce. Notwithstanding the richness and fertility of the lands of this province, a decided preference is given to plantations nearer to Recife, so that those of Paraiba are to be purchased at a much lower price. The population of this small city may amount to three thousand.

Besides the capital, this province contains seven towns in the eastern part, or that next the ocean, with a few arraials; and two in the western part. The names of those in the east are, Pilar, Alhandra, Villa Real, Villa do Con-de, Villa da Rainha, St Miguel, and Montemor; and those in the west are Pombal and Villa Nova da Souza. None of them are of any extent or material importance. Villa da Rainha, commonly called Campinha Grande, stands in an extensive plain, one hundred and twenty miles north-west from the capital, near a lake which supplies the inhabitants with water. In seasons of drought, which are by no means rare, the lake is dry, and the inhabitants are compelled to fetch their water a distance of six miles. The river Mamanguape, whose embouchure is ten miles north of Point Lucena, but dry in summer a few miles up from the sea, gives its name to a settlement near its banks, which is larger than most of the towns of the province. It is a thriving place, and forms a convenient stage between Rio Grande and Goiana. The population of Paraiba was estimated in 1812 at 122,000. From the census of 1830 it is stated at 240,000, which appears to be too large an allowance of inhabitants for such a small tract of a country so thinly peopled as Brazil is, considering its vast extent. (R. R. R.)

Paraiba, the name of a large river in the Brazilian province of Rio de Janeiro, which see.

PARALIPOMENA, in matters of literature, denotes a supplement of things omitted in a preceding work.

PARALLAX, in *Astronomy*, is the difference between the places of any celestial object, as seen from the surface and from the centre of the earth at the same instant. See Astronomy.

Parallax is also used to denote the change of place in any object arising from viewing it obliquely with respect to another object. Thus, the minute hand of a watch is said to have a parallax when it is viewed obliquely; and the difference between the instants shown by it when viewed directly and obliquely is the quantity of parallax in time.

PARALLEL, in *Geometry*, an appellation given to lines, surfaces, and bodies, which are everywhere equidistant from each other.

Parallel *Sphere*, that situation of the sphere in which the equator coincides with the horizon, and the poles with the zenith and nadir.

Parallel *Sailing*. See the article Navigation.

Parallels *of Latitude*, in *Astronomy*, are lesser circles of the sphere, parallel to the ecliptic, and imagined to pass through every degree and minute of the colures.

Parallels *of Altitude*, or *Almucantars*, are circles parallel to the horizon, imagined to pass through every degree and minute of the meridian between the horizon and zenith, and having their poles in the zenith.

Parallels *of Declination*, in *Astronomy*, are the same with parallels of latitude in geography.

PARALLELOPIPED, in *Geometry*, is a regular solid, comprehended under six parallelograms, the opposite ones of which are similar, parallel, and equal to each other.

PARALOGISM, in *Logic*, a sophism in reasoning, or a fault committed in demonstration, when a consequence is drawn from principles which are false, or, though true, are not proved; or when a proposition is passed over which should have been proved by the way.

PARAMARIBO, the principal town of Dutch Guiana, and capital of the province of Surinam. It is situated on the right bank of the beautiful river Surinam, about eighteen miles from its embouchure. It is about one mile and a half in length by about three quarters of a mile in breadth, and is built in the form of an oblong square. The streets are regularly laid out, and lined with orange, shaddock, tamarind, and lemon trees, which appear in perpetual bloom; whilst their branches are, at the same time, weighed down with fruit. The walks are covered with fine gravel and sea-shells, and not paved with large stones. The houses, which are generally of two stories in height, are sumptuously furnished. The rooms are seldom papered or plastered, but wainscoated with cedar, Brazilian, or mahogany wood. The town-hall is an elegant edifice, covered with tiles, the other buildings being for the most part roofed with thin split boards called shingles. In this hall the different courts are held; and underneath are the prisons for European delinquents. There is a Protestant church, a Lutheran chapel, and two Jewish synagogues, the one German, and the other Portuguese. Although not fortified, the town is defended by Fort Zelandia on the east, and by the natural defences of the river on the south-east, a large savannah on the west, and an impenetrable wood on the north-east. The citadel is separated from the town by a large esplanade, where the troops parade. There is a large and commodious military hospital. Opposite to the town the river Surinam is about a mile in breadth, and thus affords a noble road for shipping. The commerce of this town, although now surpassed by that carried on in British Guiana, is considerable; and the Dutch have made great and successful exertions to improve it. The exports are coffee, sugar, cocoa, cotton, and indigo; the imports are flour, beef, pork, herrings, salted mackerel, spermaceti candles, horses, lumber, and European manufactures. The number of inhabitants may be estimated at from 18,000 to 20,000.

PARAMATTA, a town of New Holland, on the east coast, situated at the head of Port Jackson harbour, at the distance of about eighteen miles by water and fifteen by land from Sydney. The river is for the last seven or eight miles navigable only for boats of twelve or fifteen tons burden. The town is built on a level plain, cleared of trees to a considerable extent, but not very fertile, along a small fresh-water stream which falls into the river. The streets are regularly laid out, crossing at right angles, and the town, or rather the rudiments of a town, may be said to be extensive, the inhabitants being estimated at 3000, and there being space enough for thrice that number. The dwellings are generally poor structures or wretched hovels. There are, however, a few good brick houses, to which is attached a garden, in which British vegetables are cultivated. The government buildings are very large; the governor's house is on the west side of the town, the factory for female convicts on the east, the orphan-school on the north, and the public granary on the south. An arm of the sea, about the breadth of a third-rate English river, stretches through the middle, and over it there is a bridge. There are two very good inns, with all necessary accommodations for travellers, such as are found in Great Britain. In the factory for female convicts, which is a large building, well adapted for the convenience and comfort of its inmates, there were above a hundred females when it was visited by the missionaries from the South Sea Islands, and about as many more were daily expected. They are employed in dressing and spinning flax and wool, to be woven into clothing materials by the men at their quarters. From this penitentiary the inhabitants of Sydney and Paramatta receive a supply of domestic servants, many of whom behave with perfect propriety. The orphan-school is an admirable establishment, where upwards of one hundred children of convicts are instructed in reading, writing, and arithmetic, and in moral habits. After being kept there till the age of fourteen or fifteen years, they are usually taken into families as servants or apprentices. There are also two schools for the education of the aborigines of the country, laudable institutions, but which have not yet been attended with much advantage, the natives being wedded to their native habits of ignorance and idleness, and having a rooted aversion to industry. There were in each seminary only seven boys and as many girls when it was visited by the South Sea missionaries. The schools are supported by government, an allowance of L.20 being made for each child taught. The population is chiefly composed of inferior traders, publicans, artificers, and labourers. Two fairs, held half yearly, are numerously and respectably attended. The plain on which the town is situated is cleared of trees to a considerable extent, and there is an excellent road through Paramatta; but beyond this the uncleared soil is covered with prodigious forests. Many farms, having been insulated from this tract, are divided into fields, and well cultivated, though the stumps of trees about a yard high are still seen standing amidst the corn and grass. The houses of the colonists, who follow agriculture each in his little domain, are generally clean and comfortable abodes, and some even have claims to elegance.

PARANA, a vast river of South America, originating in those mountainous ranges which traverse the Brazilian provinces of Minas Geraes and Goyas. Like the Paraguay, it is formed of a great number of small streams, the sources of which extend over several degrees, probably from the sixteenth to the twentieth of south latitude. Before the Parana reaches the parallel of south latitude under which the Paraguay commences, it has drained an immense tract of country, and become swelled to a mighty stream. About this point, which is the verge of the great table-land which forms the inner part of Brazil, it tumbles over a precipitous rocky channel, at a place called Setequedas, or Seven Falls. Some have spoken of a continued rapid and broken advance of the river for several leagues; but Cazal, a high authority, represents it as here narrowed from a league in breadth to a hundred yards, by six small rocky islands, between which the water rushes, foams, and falls. But the hundred yards mentioned must refer only to the breadth of that part of the river which is wholly uninterrupted by the islands; between all of them various minor currents must of course flow, and these are certainly not included in the statement of the width of the Parana at this part. Azara describes these stupendous cataracts under another name. The first, called Sant de Canendigu, which was the name of a cacique who inhabited this part of the country at the time of the conquest, and Sant de Guayra, from the vicinity of the province of that name, is situated not far from the tropic of Capricorn, in 24. 4. 27. of south latitude. It is a frightful cascade, and worthy of being described by the poets. Immediately before this immense river falls over the precipice, or rather inclined plane, it is suddenly contracted from above two hundred toises to about thirty toises in breadth, and descends into the frowning abyss with frightful fury, causing the solid earth to tremble around. The fall is not vertical, but at an angle of fifty degrees, the perpendicular descent being fifty-two French feet. The vapours which rise from the shock of the waters, and the pointed rocks situated in the channel of the precipice, are seen at the distance of many leagues, in the form of columns. Rainbows of the most lively colours, formed by the rays of the sun, appear suspended over the cataract; and in these a quivering movement may be perceived. The sound is heard at the distance of six leagues; and the clouds which are formed by the ascending vapours form an eternal rain in the vicinity. There are other cataracts either belonging to the Parana or its tributaries, but they are not of such magnitude as the Setequedas. The general bearing of the Parana, in by far the greater part of its course, is southerly. About the twenty-seventh parallel it takes a westerly direction, in which it continues to flow until its junction with the Paraguay. Not far from the point where it takes a great bend from south-west to nearly due west, it meets with a rocky edge, over which it is precipitated at the island of Apipé, and here navigation for large vessels terminates. But when the waters are large, the passage is free for galliotes and small craft. Near this is the lake Ibera or Ybyera, one of the most considerable in the country, and which, like the Xarayes of Paraguay, is said to be formed by the water of the upper part of the Parana. Azara, however, asserts that it has no connection with that river. It is thirty leagues in breadth at its northern extremity, where it is parallel with the Parana, and to which it is very near, though without having any visible communication with that river. Thirty leagues to the south, there is formed what has been called the Gorge of Yuquicua; after which it again enlarges in proportion as it advances southward, until it terminates by forming the river Miriñay, which is considerable, and flows into the Uruguay. From Yuquicua the lake Ybyera also stretches thirty leagues to the west, and there three rivers issue from it, called the Saint Lucie, the Corrientes, and the Bateles. It has no apparent source, receiving neither river nor rivulet, and continues during the year almost without any variation, being filled with aquatic plants, and even with some trees. A great part of it must therefore partake more of the character of a marsh than a lake; and it is to be observed that several recent authorities maintain that it is connected with the river Parana, and follows the rise and fall of its waters. "In the dry season," says Luccock, "it covers an extent of about a hundred and fifty square leagues, and all around the land supplies an abundance of food for cattle; but about a month after the rains have commenced in the upper country, that is, in December, the Ybyera swells to a vast extent, covering hardly less than two thousand square leagues. At this period it is said to communicate both with the Parana and the Uruguay; a circumstance which, if correctly stated, indicates that these streams once united there, and that the lower grounds have been formed by their concurrent operation continued for ages." Higher up on the same river, and in the midst of the woods, is another lake called the Jagape, but little more is known of it than its name, and that chiefly from the report of people dwelling in its neighbourhood, who occasionally find their way to Rio de Janeiro.

After the confluence of the Parana and Paraguay, in latitude 27. 27., the river under the former name assumes a grand and majestic appearance. It is studded with innumerable islands, some of which are of considerable size, thickly clothed with trees and shrubs, and forming a refuge for foxes, tigers, and other wild animals. The volume of its waters is of course very great. It is above two miles in breadth, of considerable depth, and has a current more rapid than that of the Paraguay before its junction. "The Parana and Paraguay," says Mr Luccock, "rolling impetuously through a very extended course, bring down a great quantity of wreck, and soil of a reddish colour. When they have arrived at the more level grounds, and their currents are become comparatively slow, much of it is deposited; there it remains until the next wet season, when it is again urged onward by a resistless torrent, which not only sweeps the bottom, but frets and tears the banks, which had before been raised." The main current is never less than two fathoms and a half in depth; and it is near the sides of the river, not in the centre, that the channel is deepest. Its periodical rise commences in December, which is some time after the commencement of the rainy season in the countries situated between the tropic of Capricorn and the equator; and it continues rising without interruption till the month of April, when decreasing till July, with somewhat more rapidity than it rose, it again shrinks within its legitimate bounds. In the latter month it is usual to perceive a slight rising, which the inhabitants of the country call "El repunte;" and which is attributed to the waters which the river receives from the streams pouring down from the temperate zone, where the season of winter is almost always rainy. But the "repunte" is of such trivial moment that it never overflows the lands even in the lowest situations. The rains, although invariable as to their recurrence, are greater in some years than in others; and the height to which the river rises, of course, corresponds with the quantity of rain which falls. The navigation of this river is of considerable importance. "There are three causes which regularly impede the navigation of rivers," says Don Ignacio Nuñez, in his work on the united provinces of the Rio de la Plata, "the great rapidity of their currents, the shallowness of their waters, and the shoals, rocks, or banks which obstruct their passage. None of these inconveniences are met with in the Parana, till reaching the island of Apipé. The rapidity of its course varies with the state of the river, and the conformation of its channel. When the rising is at its greatest height, the velocity of its current is greater than when it is on the decrease; and, in both seasons, it is always greatest in those parts where its channel is the narrowest. In the Rosario, in Punta Gorda, and in Hernan de Arias, which are the places where it is the most straitened in width, six observations made during the time of its rising gave for its average velocity a foot and a half per second. When the river is in its natural bed its stream has much less velocity, and that is not alike in all places in its breadth. In the centre of the channel it is greater than on the shore towards the bogs; and there, on account of its being very accessible, it is greater than in the places near the islands, where the velocity is almost null; which is not the case in the Rio de la Plata, in which the currents are invariably in proportion to, and in direction with, the winds which blow. It is therefore evident that the rapidity of the current of the Parana is no impediment to its navigation; which, indeed, experience has long since proved. As regards the depth, no person is ignorant of its capability for the navigation of vessels of all burdens as far as the island of Apipé; and it would continue with depth enough for that object for a great distance farther, did not a cataract situated in that place impede its progress." He then goes on to state, that its depth at the shallowest is quite sufficient for very large vessels; and that the greater part of its sinuosities and arms are not only navigable in the rainy season, but even when the river is at the lowest. "From Cape Saint Maria to the island of Apipé," he continues, "is a distance by water of five hundred leagues, navigable without any other reef than the English Bank (Banco Ingles), which will cease to be dangerous as soon as a vigilant and protecting government shall watch over the commerce and prosperity of the country. In the whole course of the Parana there is not a single stone; its bottom is clay and very fine sand; and although some banks and shallows are here and there met with, a sufficient channel is left at all times for the passage of vessels." In reference to the extent of country inundated, he says, "The average rising is about twelve feet; but the islands and lands subject to be overflowed never have that depth of water over them, owing to their greater height. When the river is at the highest, the lowest of the islands scarcely have more than three feet over them, and some, for the distance of many leagues, are covered by only eight or nine inches. There are also places which are not inundated except during extraordinary risings, which may not occur for a considerable length of time. There are likewise inundations so low that they form lakes, which disappear solely through evaporation and filtration, leaving a great quantity of fish out of their element. Calculating the immense extent of territory inundated by the Parana, only from its mouth to Cayasta, of which we can speak with accuracy from our own observations, its waters during the inundation cover about one thousand one hundred square leagues; and, making an approximate calculation of the whole extent of country which enjoys this beneficial circumstance, from near the tropic of Capricorn, where the river begins to assume this quality, to its mouth, the space participating in so vast an advantage, without any aid from art, may be reckoned at about four thousand leagues." A river so extensive as the Parana is of course supplied by many tributary rivers. Amongst the most considerable of these is the Salada or Salado, which rises in the province of Salta, and flows into the Parana at Santa Fé. It is navigable for many leagues, and as it traverses a very fertile country, it will one day become of far more importance than it is at present. It is to be distinguished from another river of the same name, which unites with the Rio de la Plata in latitude 36°, four or five degrees farther down. The Parana flows into the river last named by several mouths, comprehended between latitude 34. and 34. 20. south. Here also the Rio de la Plata receives the Uruguay, and these united streams flow majestically to the Atlantic Ocean. (R. R. R.)

PARANYMPH, amongst the ancients, the person who waited on the bridegroom, and directed the nuptial solemnities, and who was also called *pronubus* and *auspex*, because the ceremonies began by taking auspicia. As the paranymph officiated only on the part of the bridegroom, a woman called *pronuba* officiated on the part of the bride.

PARAPET, in *Fortification*, an elevation of earth designed for covering the soldiers from the enemy's cannon or small shot.

PARAPHERNALIA, or PARAPHERNA, in the civil law, those goods which a wife brings her husband besides her dower, and which are still to remain at her disposal, exclusive of her husband, unless there is some provision made to the contrary in the marriage-contract.

PARAPHRASE, an explanation of some text in clearer and more ample terms, by which is supplied what the author might have said or thought on the subject. Such are esteemed Erasmus's Paraphrase on the New Testament, the Chaldee Paraphrase on the Pentateuch, and other works of this kind.

PARAPHROSYNE, a word employed by medical writers to denote a delirium, or an alienation of mind in fevers, or from whatever other cause.

PARASANG, an ancient Persian measure, which differed at different times and in different places, being usually thirty, sometimes forty, and occasionally fifty stadia or furlongs. The word, according to Littleton, is formed from *parasch angarius*, that is, the space a postman rides from one station or *angaria* to another.

PARASCENIUM, in the Grecian and Roman theatres, was a place behind the scenes, whither the actors withdrew to dress and undress themselves. The Romans more frequently called it *Postscenium*.

PARASELENE, in *Natural Philosophy*, a mock moon; a meteor or phenomenon encompassing or adjacent to the moon, in form of a luminous ring; in which are observed sometimes one and sometimes two or more images of the moon.

PARASEMON, amongst the Greeks, was the figure carved on the prow of a ship, to distinguish it from others. This figure was generally that of a bull, lion, or other animal; sometimes the representation of a mountain, tree, flower, or other object.

PARASITE, amongst the Greeks, was originally a very reputable title, the parasites being a kind of priests, or at least ministers, of the gods, in the same manner as the *epulones* were at Rome. They took care of the sacred corn, or the corn destined for the service of the temples and the gods, viz. sacrifices and feasts; and they had even the superintendence of sacrifices, taking care that these were duly performed. At Athens there was a kind of college of twelve parasites; each tribe of Attica furnishing one, who was always chosen out of the best families. Polybius adds, that a parasite was also an honourable title amongst the ancient Gauls, and was given to their poets. But it has degenerated into a term of reproach, and is now used to signify a flatterer, sycophant, or mean dependent.

PARASITES, or Parasitical Plants, in *Botany*, such plants as are produced out of the trunk or branches of other plants, whence they receive their nourishment, and are incapable of growing on the ground. Such are the misletoe, some kinds of fungi, and others.

PARBUNCLE, in a ship, the name of a rope almost like a pair of slings. It is seized both ends together, and then put almost double about any heavy thing that is to be hoisted in or out of the ship; having the hook of the runner hitched into it to hoist it up by.

PARCÆ, in heathen mythology, goddesses who were supposed to preside over the accidents and events, and to determine the date or period, of human life. The Parcæ were three, Clotho, Lachesis, and Atropos; because, forsooth, all things have their beginning, progress, and end. Hence the poets tell us that the Parcæ spun the thread of men's lives; that Clotho held the distaff, and drew the thread; that Lachesis twirled the spindle, and spun it; and that Atropos cut it. "Clotho colum retinet, Lachesis net, Atropos secat."

But the ancients represent the Parcæ differently. Lucian delineates them in the shape of three poor old women, having large locks of wool, mixed with daffodils, on their heads; one of them holding a distaff, the other a wheel, and the third a pair of scissars, wherewith to cut the thread of life. Others represent Clotho as appearing in a long robe of variegated colours, wearing a crown upon her head adorned with seven stars, and holding a distaff in her hand; whilst Lachesis appears in a robe beset with stars, with several spindles in her hand, and Atropos clad in black, cutting the thread with a pair of large scissars. The ancients imagined that the Parcæ employed white wool for a long and happy life, and black for a short and unfortunate one.

PARCHMENT, the skins of sheep or goats prepared after such a manner as to render them proper for being written upon, or used in covering books.

The word comes from the Latin *pergamena*, the ancient name of this manufacture, which is said to have been taken from the city of Pergamus, to Eumenes, the king of which, its invention is usually ascribed; although, in reality, that prince appears rather to have been the improver than the inventor of parchment. According to Diodorus, the Persians of old wrote all their records on skins; and the ancient Ionians, as we learn from Herodotus, made use of sheep and goat skins in writing, many ages before the time of Eumenes. Nor need we doubt that such skins were dressed for the purpose, after a manner not unlike that in which our parchment is prepared, though probably not so artificially.

The manufacture of parchment is begun by the skinner, and finished by the parchment-maker. The skin having been stripped of its wool, and placed in the lime-pit, the skinner stretches it on a kind of frame, and pares off the flesh with an iron instrument. This being done, it is moistened with a rag; and powdered chalk being spread over it, the skinner takes a large pumice-stone, flat at the bottom, rubs over the skin, and thus scours off the flesh: he then goes over it again with an iron instrument, moistens it as before, and rubs it again with the pumice-stone without any chalk underneath, by which means the flesh side is very considerably smoothed and softened. He then drains it again, by passing over it the iron instrument as before. The flesh side being thus drained, by scraping off the moisture, he in the same manner passes the iron over the woolly or hairy side, and then stretches it on a frame, and scrapes the flesh side again. This finishes its draining; and the more it is drained the whiter it becomes. The skinner now throws on more chalk, sweeping it over with a piece of lamb-skin which has the wool on; and this smooths it still farther. It is then left to dry, and when dried, taken off the frame by cutting it all round. The skin, being thus far prepared by the skinner, is taken out of his hands by the parchment-maker, who first, whilst it is dry, pares it on a *summer*, or calf-skin stretched in a frame, with a sharper instrument than that used by the skinner; and, working with the arm from the top to the bottom of the skin, takes away about one half of its thickness. The skin, being thus equally pared on the flesh side, is again rendered smooth by being rubbed with the pumice-stone on a bench covered with a sack stuffed with flocks, which leaves the parchment in a condition fit for writing upon. The parings thus taken off the leather are used in making glue, size, and the like.

What is called *vellum* is only parchment made of the skins of abortives, or at least sucking calves. This has a much finer grain, and is whiter and smoother than parchment; but it is prepared in the same manner, except that it is not passed through the lime-pit.

PARDIES, Ignatius Gaston, an ingenious and learned French Jesuit, was born at Paris in 1636. He taught polite literature for several years, during which he composed, with peculiar delicacy of thought and style, small pieces both in prose and verse. At length he devoted himself entirely to mathematics and natural philosophy, and read all authors, ancient as well as modern, in those branches of knowledge. He died in the year 1673, of an infectious disorder contracted by confessing and preaching to the prisoners in the Bicêtre during the Easter holidays. Pardies published several works; but his Elements of Geometry are best known in this country, where a translation of them has gone through several editions. In 1672 he had a dispute with Sir Isaac Newton respecting the theory of light and colours, of which an account may be seen in the Philosophical Transactions for that year.

PARDON, in *Criminal Law*, is the remitting or forgiving an offence committed against the king.

Law, says Beccaria, cannot be framed on principles of compassion to guilt; yet justice, by the constitution of England, is bound to be administered in mercy. This is promised by the king in his coronation oath; and it is that act of his government which is the most personal and most entirely his own. The king condemns no man; that unpleasant task he leaves to his courts of justice; the great operation of his sceptre is mercy. His power of pardoning was said by the Saxons to be derived *a lege suæ dignitatis*; and it is declared in parliament, by stat. 27 Henry VIII. c. 24, that no other person has power to pardon or remit any treason or felonies whatsoever, but that the king has the whole and sole power thereof, united and knit to the imperial crown of this realm.

Mr Godwin, in his Inquiry concerning Political Justice, attacks this prerogative in the following terms: "What is the rule that ought in all cases to prescribe to my conduct? Surely justice; understanding by justice the greatest utility of the whole mass of things that may be influenced by my conduct. What then is clemency? It can be nothing but the pitiable egotism of him who imagines he can do something better than justice. Is it right that I should suffer constraint for a certain offence? The rectitude of my suffering must be founded on its tendency to promote the general welfare. He therefore that pardons me, iniquitously prefers the imaginary interest of an individual, and utterly neglects what he owes to the whole. He bestows that which I ought not to receive, and which he has no right to give. Is it right, on the contrary, that I should not undergo the suffering in question? Will he, by rescuing me from suffering, do a benefit to me, and no injury to others? He will then be a notorious delinquent, if he allow me to suffer. There is indeed a considerable defect in this last supposition. If, while he benefits me, he do no injury to others, he is infallibly performing a public service. If I suffered in the arbitrary manner which the supposition includes, the whole would sustain an unquestionable injury in the injustice that was perpetrated. And yet the man who prevents this odious injustice has been accustomed to arrogate to himself the attribute of clement, and the apparently sublime, but in reality tyrannical, name of forgiveness. For, if he do more than has been here described, instead of glory he ought to take shame to himself, as an enemy to the interest of human kind. If every action, and especially every action in which the happiness of a rational being is concerned, be susceptible of a certain rule, then caprice must be in all cases excluded; there can be no action which, if I neglect, I shall have discharged my duty; and if I perform, I shall be entitled to applause."

That human nature is such as in the aggregate to need control, no one who is acquainted with it will deny; and there appears to be no other method of controlling mankind but by general laws, which, through the natural imperfection of human affairs, may be cruel in one case if they are just in another. Cases may likewise occur where the sentence of the law, without its execution, will answer every purpose which could be expected from it, and where the execution of it would be extreme cruelty, although it might in strict unfeeling language be called justice, because in strict conformity with the letter of the law. Yet though such cases may and do often occur, it would be absurd to abolish any of those laws which the security of civil society has required; and therefore the only natural remedy against legal injustice is the system of pardons.

Mr Godwin next goes on to trace the origin of pardons; and instead of a definite system of law, we are told that it is necessary to have a court of reason, to which the decisions of a court of law shall be brought for revisal. But this is a remedy apparently too vague and indeterminate to produce any lasting or good effect; for the proposal of such a tribunal results from supposing mankind more virtuous and intelligent than they really are. He next proceeds to consider the abuses of pardons, whence he would draw an argument for their abolition. He tells us that the authority in this case is placed, first in the judge, and next in the king and council. "Now," says he, "laying aside the propriety or impropriety of this particular selection, there is one grievous abuse which ought to strike the most superficial observer. Those persons with whom the principal trust is reposed consider their functions in this respect as a matter purely incidental, exercise them with supineness, and in many instances with the most scanty materials to guide their judgment. This grows in a considerable degree out of the very name of pardon, which implies a work of supererogatory benevolence."

But it is obvious that pardons are in general granted in consequence of an application from people who have more than scanty materials to guide their judgments, and on whose fidelity in relating the circumstances of the case confidence is or is not placed, according to their several characters. Mr Godwin next proceeds to the arbitrary character of pardons. "Such a system," he says, "to speak it truly, is a lottery of death, in which each man draws his ticket for reprieve or execution, as undefinable accidents shall decide." The allusion here to a lottery ticket is peculiarly unfortunate, nor does the whole sentence show any great degree of candour. It is possible to define a particular crime, and to annex a particular punishment to the commission of it; but the nature of morality consists not in the external action, but in the motives which prompted to it. Definite law, however, cannot always make this distinction; and after the sentence of the law is pronounced, it comes to be considered whether there are any alleviating circumstances in the case; and whether there are or not, must depend on the particulars or accidents of the case. But it is impossible to suppose that these accidents could be previously defined; their nature does not admit of it. To particularize and define every mode of an action which imagination can conceive, or which experience has shown us may happen, would indeed be an Herculean labour; and we might literally say with the apostle, "that the world could not contain the books that might be written." We are, however, told that "reason is a thousand times more explicit and intelligible than law; and when we are accustomed to consult her, the certainty of her decisions would be such as men practised in our present courts are totally unable to conceive." Were reason, however, to be appealed to in all cases, and to be the final criterion, it would leave far greater room for villany than any mode at present in practice. Reason is a very uncertain and indefinite term, and may be made any thing, according to the circumstances or passions of men, at any given time.

We are next told that pardons are destructive to morality. "Another very important consequence," says Mr Godwin, "grows out of the system of pardons. A system of pardon is a system of unmitigated slavery. I am taught to expect a certain desirable event. From what? From the clemency, the uncontrolled, unmerited kindness of a fellow-mortal. Can any lesson be more degrading? The pusillanimous servility of the man who devotes himself with everlasting obsequiousness to another, because that other, having begun to be unjust, relents in his career,—the ardour with which he confesses the rectitude of his sentence and the enormity of his deserts,—will constitute a tale that future ages will find it difficult to understand. What are the sentiments in this respect that are alone worthy of a rational being? Give me that, and that only, which without injustice you cannot refuse. More than justice it would be disgraceful for me to ask, and for you to bestow. I stand upon the foundation of right. This is a title which brute force may refuse to acknowledge, but which all the force in the world cannot annihilate. By resisting this plea you may prove yourself unjust, but in yielding to it you grant me but my due. If, all things considered, I be the fit subject of a benefit, the benefit is merited; merit in any other sense is contradictory and absurd. If you bestow upon me unmerited advantage, you are a recreant from the general good. I may be base enough to thank you; but if I were virtuous I should condemn you. These sentiments alone are consistent with true independence of mind. He that is accustomed to regard virtue as an affair of favour and grace, cannot be eminently virtuous. If he occasionally perform an action of apparent kindness, he will applaud the generosity of his sentiments; and if he abstain, he will acquit himself with the question, May I not do what I will with my own? In the same manner, when he is treated benevolently by another, he will in the first place be unwilling to examine strictly into the reasonableness of this treatment, because benevolence, as he imagines, is not subject to any inflexibility of rule; and, in the second place, he will not regard his benefactor with that erect and unembarrassed mien, that complete sense of equality, which is the only immoveable basis of virtue and happiness."

Such being Mr Godwin's conclusion on this subject, we leave it with our readers to determine whether his system or that which we at present enjoy would be the more rigorous or unjust; or whether mankind have indeed arrived at so eminent a pitch of virtue as to disdain every favour which they do not absolutely merit. The Christian religion speaks a very different language.

PAREENUGGUR, a town of Hindustan, in the province of Cutch, and district of Parkur. It was formerly a place of great consequence, and celebrated for its temples, which were dedicated to Buddha. It now contains only 300 houses, chiefly inhabited by Sodah Rajpoots; its ancient inhabitants having long ago left it, on account of the turbulent state of the country, and migrated for safety to Noanagur and other places. The town is not fortified; and when it is attacked, the inhabitants fly for refuge to a neighbouring mountain, which is represented as rising to a great elevation. During the era of its prosperity, which was at a remote period, it was inhabited by numerous families of Banyans, whose temples were famous for elegance and sanctity, and were resorted to from every quarter for the purposes of devotion. The idol of stone, Goreecha, was an object of adoration to multitudes, who resorted thither from all quarters.

PAREGORICS, in *Pharmacy*, medicines that assuage pain, and are otherwise called Anodynes.

PARELCON, in *Grammar*, a figure by which a word or syllable is added to the end of another.

PAREMBOLE, in *Rhetoric*, a figure in which something relating to the subject is inserted in the middle of a period. According to Vossius, all the difference between the parembole and parenthesis is, that the former relates to the subject in hand, whereas the latter is foreign to it.

PARENT, a term of relation applicable to those from whom we immediately derive our being. To this subject belongs an inquiry, first, into the legal duties of parents to their legitimate children, and, secondly, their power over them.

I. The duties of parents to legitimate children consist in their maintenance, protection, and education. The duty of parents to provide for the maintenance of their children, is a principle of natural law, an obligation laid on them not only by nature herself, but by their own proper act, in bringing them into the world; for they would be in the highest degree injurious to their issue, if they only gave their children life, that they might afterwards see them perish. By begetting them, therefore, they have entered into a voluntary obligation to take care that the life which they have bestowed shall be supported and preserved. And thus the children have a perfect right to receive maintenance from their parents. The president Montesquieu justly observes upon this head, that the establishment of marriage, in all civilized states, is built on the natural obligation of the father to provide for his children, for that ascertains and makes known the person who is bound to fulfil this obligation; whereas, in promiscuous and illicit conjunctions, the father is unknown, and the mother finds a thousand obstacles in her way, shame, remorse, the constraint of her sex, and the rigour of laws, which stifle her inclinations to perform this duty; and, besides she generally wants the ability to do so.

The municipal laws of all well-regulated states have taken care to enforce this duty, though Providence has done it more effectually than any laws, by implanting in the breast of every parent that natural σοργη, or affection, which neither the deformity of person or mind, nor even the wickedness, ingratitude, and rebellion of children, can totally suppress or extinguish.

The civil law obliges the parent to provide maintenance for his child; and if he refuse, *judex de ea re cognoscet.* Nay, it carries this matter so far, that it will not suffer a parent at his death totally to disinherit his child, without expressly giving his reason for so doing; and there are fourteen reasons reckoned up, which may justify such disinherison. If the parent alleged no reason, or a bad one, the child might set the will aside, *tanquam testamentum inofficiosum,* as a testament contrary to the natural duty of the parent, by suggesting that the parent had lost the use of his reason when he made the *inofficious* testament. And this, as Puffendorff observes, was not to bring into dispute the testator's power of disinheriting his own offspring, but to examine the motives upon which he did it, and if they were found defective in reason, then to set them aside. But perhaps this is going rather too far. Every man has, or ought to have, by the laws of society, a power over his own property; and, as Grotius very well distinguishes, natural right obliges to give a necessary maintenance to children; but what is more than that they have no other right to, than as it is given by the favour of their parents, or the positive constitutions of the municipal law.

Let us next see what provision our own laws have made for this natural duty. It is a principle of law, that there is an obligation on every man to provide for those descended from his loins; and the manner in which this obligation shall be performed is thus pointed out.

The father and mother, grandfather and grandmother, of poor impotent persons, shall maintain them at their own charges, if of sufficient ability, according as the quarter sessions shall direct; and if a parent run away and leave his children, the church wardens and overseers of the parish shall seize his rents, goods, and chattels, and dispose of them towards their relief. By the interpretations which the courts of law have put upon these statutes, if a mother or grandmother marry again, and before such second marriage had sufficient ability to keep the child, the husband shall be charged to maintain it; for this being a debt of his wife when single, shall, like others, extend to the charge of the husband. But at her death, the relation being dissolved, the husband is under no farther obligation.

No person is bound to provide a maintenance for his issue, unless where the children are impotent and unable to work, either through infancy, disease, or accident; and then he is only obliged to find them in necessaries, the penalty on refusal being no more than twenty shillings a month. For the policy of our laws, which are ever watchful to promote industry, did not mean to compel a father to maintain his idle and lazy children in ease and indolence, but thought it unjust to oblige the parent, against his will, to provide them with superfluities, and other indulgencies of fortune; imagining they might trust to the impulse of nature, if the children were deserving of such favours. Yet, as nothing is so apt to stifle the calls of nature as religious bigotry, it is enacted, that if any Popish parent shall refuse to allow his Protestant child a fitting maintenance, with a view to compel him to change his religion, the Lord Chancellor shall by order of court constrain him to do what is just and reasonable. But this did not extend to persons of another religion, of no less bitterness and bigotry than the Popish; and therefore, in the very next year, we find an instance of a Jew of immense riches, whose only daughter having embraced Christianity, he turned her out of doors; and on her application for relief, it was held that she was entitled to none. But this gave occasion to another statute, which ordains, that if Jewish parents refuse to allow their Protestant children a fitting maintenance, suitable to the fortune of the parents, the Lord Chancellor, on complaint, may make such order therein as he shall see proper.

Our law has made no provision to prevent the disinheriting of children by will, leaving every man's property in his own disposal, upon a principle of liberty in this as well as every other action, although perhaps it would not have been amiss if the parent had been bound to leave them at the least a necessary subsistence. Indeed, amongst persons of any rank or fortune, a competence is generally provided for younger children, and the bulk of the estate settled upon the eldest by the marriage articles. Heirs, also, and children, are favourites of our courts of justice, and cannot be disinherited by any dubious or ambiguous words; there being required the utmost certainty of the testator's intentions to take away the right of an heir.

From the duty of maintenance we may easily pass to that of protection, which is also a natural duty, but rather permitted than enjoined by any municipal laws; nature, in this respect, working so strongly as to need rather a check than a spur. A parent may, by our laws, maintain and uphold his children in their law-suits, without being guilty of the legal crime of maintaining quarrels. A parent may also justify an assault and battery in defence of the persons of his children. Nay, where a man's son was beaten by another boy, and the father went near a mile to find him, and there revenged his son's quarrel by beating the other boy, of which beating he afterwards unfortunately died, it was not held to be murder, but only manslaughter. Such indulgence does the law show to the frailty of human nature, and the workings of parental affection.

The last duty of parents to their children is that of giving them an education suitable to their station in life; a duty pointed out by reason, and one of the greatest importance. For it is not easy to imagine that a parent has conferred any considerable benefit upon his child by bringing him into the world, if he afterwards entirely neglect his culture and education, and suffer him to grow up like a mere beast, or to lead a life useless to others and shameful to himself. Yet the municipal laws of most countries seem to be defective in this point, by not constraining the parent to bestow a proper education upon his children. Perhaps they thought it punishment enough to leave the parent who neglects the instruction of his family to labour under those griefs and inconveniences which his family, so uninstructed, will be sure to bring upon him. Our laws, though their defects in this particular cannot be denied, have in one instance made a wise provision for breeding up the rising generation, since the poor and laborious part of the community, when past the age of nurture, are taken out of the hands of their parents, by the statutes for apprenticing poor children, and are placed out by the public in such a manner as may render their abilities, in their several stations, of the greatest advantage to the commonwealth. The rich, indeed, are left at their own option whether they will breed up their children to be the ornament or the disgrace of their family.

II. The power of parents over their children is derived from the former consideration, their duty; this authority being given them, partly to enable the parent more effectually to perform his duty, and partly as a recompense for his care and trouble in the faithful discharge of it. Upon this point the municipal laws of some nations have given a much larger authority to the parents than others. The ancient Roman laws gave the father a power of life and death over his children, upon the principle, that he who gave had also the power of taking away. But the rigour of these laws was so softened by subsequent constitutions, that we find a father banished by the Emperor Hadrian for killing his son, although he had committed a very heinous crime; upon the maxim, that the *patria potestas in pietate debet, non in atrocitate, consistere.* But still they maintained to the last a very large and absolute authority; for a son could not acquire any property of his own during the life of his father; and all his acquisitions, or at least the profits of them, belonged to the father during his life.

The power of a parent by the English law is much more moderate, but is still sufficient to keep the child in order and obedience. He may lawfully correct his child, being under age, in a reasonable manner; because this is for the benefit of his education. The consent or concurrence of the parent to the marriage of his child under age was also directed by our ancient law to be obtained; but it is now absolutely necessary, for without it the contract is void. And this is also another means which the law has put into the parent's hands, in order the better to discharge his duty; first, of protecting his children from the snares of artful and designing persons; and, next, of settling them properly in life, by preventing the evil consequences of too early and precipitate marriages. A father has no other power over his son's estate than as his trustee or guardian; for although he may receive the profits during the child's minority, yet he must account for them when the child comes of age. He may indeed have the benefit of his children's labour whilst they live with him and are maintained by him; but this is no more than he is entitled to from his apprentices or servants. The legal power of a father (for a mother, as such, is entitled to no power, but only to reverence and respect) over the persons of his children ceases at the age of twenty-one; for they are then enfranchised by arriving at years of discretion, or that point which the law has established, when the empire of the father or other guardian gives places to the empire of reason. Yet till that age arrives the empire of the father continues even after his death, for he may by his will appoint a guardian to his children. He may also delegate part of his parental authority, during his life, to the tutor or schoolmaster of his child, who is then *in loco parentis,* and has such a portion of the power of the parent committed to his charge, namely, that of restraint and correction, as may be necessary to answer the purposes for which he is employed.

PARENTALIA, in *Antiquity,* funeral obsequies, or the last duties paid by children to their deceased parents.

PARENTHESIS, in *Grammar,* means certain intercalary words inserted in a discourse, which interrupt the sense, but nevertheless seem necessary for the better understanding of the subject.

PARGA, a town of Greece, situated on the coast of Albania, fourteen miles from Cape Bianco, and ten from Paxos. It is built on a conical rock about 250 feet above the level of the sea, which surrounds it on three sides, and, with a fortress on the narrow neck which joins it to the main, forms a strong post. The territory around extends two or three miles in a circle, and till 1818 was inhabited by a population of from 3000 to 4000 persons, who had cultivated the soil with equal care and success. They were mostly persons who had established themselves there in opposition to Ali Pasha, who reigned absolute master of Albania, under the nominal authority of the Grand Signior. These people wished to place themselves under the protection of the British government; but the terms upon which they stood with Ali prevented an honourable acceptance of their proposal. After some warlike demonstrations, which were followed by negotiations, Ali agreed, on the place being given up to him, to pay the large sum of L.200,000 to the inhabitants, and give them permission to leave the territory. This most of them embraced, and were removed to the islands where British protection afforded them security. Long. 20. 23. 30. E. Lat. 39. 16. 15. N.

PARHELION, or PARHELIUM, formed from παρα, *near,* and ἥλιος, *sun,* in *Natural Philosophy,* a mock sun or meteor, in the form of a very bright light, appearing on the one side of the sun.

Appearances of this kind have been mentioned both by the ancients and by the moderns. Aristotle observes, that in general they are seen only when the sun is near the horizon, though he takes notice of two which were observed in the Bosphorus from morning to evening; and Pliny has related the occasions when such phenomena appeared at Rome. Gassendi says, that in 1635 and 1636 he often saw one mock sun. Two were observed by M. de la Hire in 1689, and the same number by Cassini in 1693, Mr Grey in 1700, and Dr Halley in 1702; but the most celebrated appearances of this kind were seen at Rome by Scheiner, at Utrecht by Muschenbroeck, and at Sedan by Hevelius. By the two former four mock suns were observed, and by the latter seven.

Parhelion.

Parhelia are apparently of the same size with the sun, though not always of the same brightness, nor even of the same shape; and when a number appear at once, there is in both these respects some difference amongst them. Externally they are tinged with colours like the rainbow, and many have a long fiery tail opposite to the sun, but paler towards the extremity. Parhelia are generally accompanied with coronas, some of which are tinged with rainbow colours, but others are white. They differ in number and size; but all agree in point of breadth, which is that of the apparent diameter of the sun.

A very large white circle, parallel to the horizon, generally passes through all the parhelia; and, if it were entire, it would run through the centre of the sun. Sometimes there are arcs of lesser circles concentric to this, touching those coloured circles which surround the sun. They are also tinged with colours, and contain other parhelia. Other circles are said to have been seen obliquely situated with respect to all those we have mentioned; but of these we have met with no authentic account. The order of the colours in these circles is the same as in the rainbow; but on the inside, with respect to the sun, they are red, as is also observed in many other coronas. Parhelia have been visible for one, two, three, and four hours together; and in North America they are said to continue several days, and to be visible from sunrise to sunset.

When the parhelia disappear, it sometimes rains, or there falls snow in the form of oblong spiculæ, as Maraldi, Weidler, Krafft, and others, have observed; and in fact the air in North America abounds with such frozen spiculæ, which are even visible to the eye. According to Ellis and Middleton, such particles have been supposed to be the cause of all coronas and parhelia.

Mr Ellis says, that at Churchill, in Hudson's Bay, the rising of the sun is always preceded by two long streams of red light, one on each side of him, and about 20° distant from him. These rise as the sun rises; and as they grow longer they begin to bend towards each other, till they meet directly over the sun, just as he rises, forming there a kind of parhelion or mock sun. These two streams of light, he says, appear to have their source in two other parhelia, which rise with the true sun; and in the winter season, when the sun never rises above the haze or fog which is constantly found near the horizon, all these accompany him during the day, and set with him in the same manner as they rise. Once or twice Mr Ellis saw a fourth parhelion directly under the true sun; but this, it seems, is not common. These facts being constant, are very valuable, and may throw great light on the theory of such remarkable phenomena.

Sometimes parhelia appear in a different manner; as when three suns have been seen in the same vertical circle, well defined, and touching one another. The true sun was in the middle, the lowest touched the horizon, and they set one after the other. This appearance was seen by M. Maleziew in 1722, and others similar to it have been related by M. Musschenbroeck.

Sometimes the sun has been observed to rise or set with a luminous tail projecting from him, of the same breadth with his diameter, and perpendicular to the horizon. Such an appearance was observed by Cassini in 1672 and 1692, by De la Hire in 1702, and by Mr Ellis in Hudson's Bay. As M. Feuillée was walking on the banks of the river La Plata, he saw the sun rising over the river with a luminous tail projecting downwards, which continued till he had attained an altitude of six degrees.

Paraselenæ, or mock moons, have also been observed, accompanied with tails and coloured circles, like those which accompany the parhelia. An account of several of these, and in particular a description of a fine appearance of the same kind, may be found in Musschenbroeck.

Various hypotheses have been framed by philosophers to account for this phenomenon, more particularly by Marriotte, Descartes, and Huygens. None of these, however, seems satisfactory; but those readers who wish to become acquainted with them may consult Huygens's Dissertation on this subject, in Smith's Optics (book i. chap. xi.), Musschenbroeck's Introduction (vol. xi. p. 1038, &c. 4to); and Dr Priestley's History of Vision, Light, and Colours (vol. ii. p. 613, et seq.).

Paria.

PARIA, a province of Bolivia, in South America, situated in the department of Oruro. On the north and north-east it is bounded by the provinces of Pacajes and Oruro, on the east and south-east by Porco, on the south-west by Lipes, and on the west by Caranjas. This province is traversed by a rapid river called the Desaguadero, or Drain, which is invariably represented in maps of Peru and Bolivia as flowing into the lake of Titicaca, whilst the reverse is the fact. It issues from this celebrated sheet of water, and, after flowing a considerable distance, its waters are dissipated by spontaneous evaporation. The province of Paria is situated in a mountainous tract of country, and being very elevated, the temperature is consequently cold. Like Oruro and other provinces in this region, it is a mining district, and contains several mines of silver. There are some lakes in the province, from which salt is extracted; and also some hot springs. The lake of Paria is from three to four leagues in length and two in width, and abounds in excellent fish. Alcedo says that it has a whirlpool, which sucks down floating bodies, and finds a passage to the sea under the cordillera, and through the shore, close to the port of Iqueique. In 1748 its waters rose to an immense height, a phenomenon which Alcedo attributes to the stoppage of its subterranean passage; but this was far more likely to arise from volcanic agency, so frequent in this country, raising and depressing the land in various directions. Farming operations are carried on in Paria, but little grain is produced; the rearing of cattle, which are plentiful, chiefly occupying the attention of the inhabitants. The cheese made here of sheep's milk is esteemed a great delicacy, and is much sought after. The capital of the province, which bears the same name, is situated 210 miles west-north-west of Chuquisaca, in 18° 50′ south latitude, and 68° 20′ west longitude. The population amounts to 50,000, of which number 37,000 are Indians, and 13,000 Creoles.

Paria, *Gulf of*, a gulf of South America, situated to the north-west of the embouchure of the river Orinoco, and having on the west the province of Cumana, and on the east the large island of Trinidad. On Terra Firma, and north-west from the mouths of the Orinoco, a peninsula or neck of land projects towards the east, in the exact direction of another but much smaller neck of land which juts out from the north-western extremity of the island of Trinidad. These projections approach within a few leagues of each other, but the passage is interrupted by two or three islands, which, from their relative position, form four openings called Boccas del Drago, or the Mouths of the Dragon. Again, at the south-western extremity of Trinidad, a neck of land advances in a westerly direction, towards a part of the delta of the Orinoco, and approaches to within twelve or fourteen miles of it. This passage is likewise interrupted by islands, and is called the Serpent's Mouth. Thus the mainland embosoms an immense bay, whilst the island of Trinidad, which lies at its mouth, forms also a bay, facing the other, by its northern and southern extremities projecting forwards. Both shores thus bend and mutually approach each other, so as to form two comparatively narrow entrances, by which the waters of the gulf communicate with those of the ocean. The Gulf of Paria, at its widest part, that is, from the shores of Trinidad to those of Colombia, is eighty-three miles across. In the other direction, from the Bocca on the south to the Boccas del Drago on the north, it measures forty-three miles. In depth it varies from eight to thirty fathoms; but there is anchorage throughout its whole extent, though on the coast of Paria its soundings are much less. On the south side of the Serpent's Mouth, which communicates with the Atlantic Ocean, and receives in the rainy season the vast flood of waters which pour as from an inland ocean through the mouths of the Orinoco, a considerable current is found setting into the gulf, which is thus reported to have its waters raised four or five inches above their usual level. The surface-water at this time, which is during the months of July, August, and September, is also said to be fresh. This is by no means an unlikely circumstance, arising from the inferior specific gravity of fresh water as compared with that of the sea; and the surface of the gulf will also continue a longer time partially fresh, from its being embayed on all sides by land, so as to shut out the swell and agitation of the ocean, which would cause a more rapid commixture of the fresh and salt water. It was this current which Columbus encountered, and which gave him so unfavourable an opinion of the Gulf of Paria, which he accordingly called the Melancholy Gulf. It is of course most violent during the rainy months; but a current generally sets into the gulf through the Serpent's Mouth to the northward during the dry season; it is, however, partial and unimportant. In the months of December, January, and February the tide sets through the Dragon's Mouth from the northward, by which the current is occasionally overpowered. The water of the Gulf of Paria is generally of a turbid and dull green cast, but in the interior it presents everywhere a tranquil and glassy surface. The winds are in general light, never increasing to more than a gentle breeze, excepting in autumn, when a few transient squalls disturb its serenity. It may indeed be regarded as a spacious harbour, affording secure anchorage in all its parts, and perfectly free from gales, storms, and accidents; for if vessels happen to get aground, the soft muddy bottom receives them without injury. The nights are generally calm and quiet, the principal annoyance to the mariner being the want of wind; so that coasting along the shores of the gulf is extremely troublesome and tedious. Its waters abound with various kinds of fish; and numerous flocks of terns and pelicans may at all seasons be seen here and there, busily employed in catching their prey. The western shore of the gulf, which forms part of a province of Colombia formerly called Paria, is remarkable for its fertility and beauty. Columbus spoke with rapture of this luxuriant land, and in his enthusiasm he concluded that it was the terrestrial paradise which had received the progenitor of the human race pure from his Creator's hands. (See the article Orinoco.) The point of the peninsula, which runs for a great many leagues into the sea opposite the island of Trinidad, is called Point Paria, and is situated in latitude 9. 12. north, and longitude 62. 1. west from Greenwich.

PARIAN Chronicle. See Arundelian Marbles.

PARIAS, or Pariahs, a tribe of Hindus, so peculiarly distinguished from all others, that they live by themselves in the outskirts of towns; and, in the country, build their houses apart from the villages, or rather have villages of their own, furnished with wells. They dare not so much as fetch water from those which other families make use of; and, lest the latter should inadvertently go to one of theirs, they are obliged to scatter the bones of dead cattle about their wells, that they may be known. See Hindustan.

PARINACOCHAS, a province of Peru, in the department of Ayachucho. It has an elevated situation in that part of the chain of the Andes which sweeps down in a circular form towards Arequipa. The temperature therefore is throughout cold, with the exception of some hollows amongst the mountains, where it is comparatively mild; and grain, herbs, and fruits, are produced in abundance. The mountains abound in mines of silver and of gold. The pasture of this province is plentiful, and of excellent quality; and numerous herds of cattle, and flocks of sheep and goats, are reared in the plains and the valleys. In the more elevated parts there are abundance of guanucas, or Peruvian camels. The chief occupations of the inhabitants consist in superintending their live stock, and manufacturing woollen cloths. In this province there is a lake called Parinacocha, seven leagues in length by about one in breadth, and in which a white bird of the name of *panuira* breeds. This name has been corrupted into Parina, and the word *cocha* or lake being added, has given rise to the designation of the province. The chief town is called Pausa, but it does not appear to be a place of any importance. The population, about 12,000 souls, is dispersed in some thirty settlements.

PARIS, the capital of France, is built on a plain watered by the river Seine, which intersects the city, and is situated in 48. 50. north latitude, and 2. 20. east longitude.

Origin and history.

The origin of Paris is enveloped in total obscurity. The first mention we find made of it is in the Commentaries of Cæsar, in whose time, about half a century before the birth of Christ, it was the chief city of the Parisii, one of the numerous Celtic tribes by whom Gaul was at that time inhabited. It was then entirely confined to the small island in the Seine now called the Cité, or the Ile du Palais. The houses which covered this small spot were, as Cæsar informs us, of the most humble order, being composed merely of mud, with straw roofs, and without chimneys. When the Gauls, then newly and but partially subdued, rose in general revolt against their Roman conquerors in the year 53 before Christ, Labienus, one of the lieutenants of Cæsar, marched against the capital of the Parisii, then called Lutetia, in the neighbourhood of which the revolted tribes had assembled in great force. An obstinate conflict ensued, and the Parisians fought with the fury of despair; but their undisciplined valour was unable to withstand the scientific tactics of the Roman legions. They were routed with great slaughter; and the general, with all his chiefs, and the greater part of his followers, were left amongst the slain. This battle appears to have been fought about four miles to the west of the Ile du Palais, but on which bank of the river the brevity of Cæsar's narrative leaves doubtful.

We find no further mention made of Paris till four hundred years after the time of Cæsar. The next notice of it is contained in the curious work of the Emperor Julian, entitled *Misopogon*, in which he speaks of having spent a winter in that town. This was in the year 358. Julian describes Paris, which he calls his dear Lutetia, as the little capital of the Parisii, and as situated on a small island rising from the river, which surrounded it on every side. It was in Paris that Julian's soldiers, two years afterwards, forced him to assume the imperial dignity, when the messengers arrived from Constans in order to recall him from the government of Gaul, which he then held. The Emperors Valentinian and Valens also passed the winter of the year 365 in Paris. Here the former issued many of his celebrated decrees; and Gratian, his son, lost, under its walls, a battle against Maximus, which cost him his empire and his life. In the year 486 this city passed from the dominion of the Romans to that of the Franks; and early in the subsequent century it was established as the capital of that people, who changed its name from Lutetia to Parisii or Parisea. Christianity had already been introduced amongst the Parisians by St Denis, about the year 250; and during the existence of the Merovingian race of princes, who governed France for a period of above two centuries and a half, numerous churches were erected, both within the city of Paris, and on the ground to the north and south of the river; whilst the buildings on the Ile du Palais, which still constituted all that was properly called Paris, were now likewise surrounded by a wall. The Merovingian race of kings was supplanted, about the middle of the eighth century, by Pepin, surnamed Le Brêf, the father of the celebrated Charlemagne. Under the Carlovingian dynasty, the extension of Paris was greatly checked by the disturbed state of the kingdom, and especially by the predatory attacks of the Normans, who, between the years 845 and 885, ravaged or besieged the city no fewer than four times. Few of the princes of the second dynasty resided at Paris, and under their feeble sway it became the patrimony of one of the great barons, who thence assumed the title of Count of Paris. Towards the close of the ninth century, it was erected into a new fief under the name of the Duchy of France; and in the year 987, Hugh Capet, who held this honour by inheritance from his ancestors, was, on the death of Louis V., elected by the other nobles to fill the vacant throne. Under the Capetian dynasty, Paris, which had now become once more the capital of France, and the principal residence of the monarch, extended itself rapidly. The ancient privileges of the citizens were confirmed, and many new immunitics were granted them. Paris, however, appears to have been without any regular municipal government until the year 1060; but Philip I., soon after his ascension to the throne, appointed a provost to maintain that superintendence over the city which had formerly been exercised by the Dukes of France. During the reign of Philip's son, Louis le Gros, the schools of Paris first acquired celebrity. For this they appear to have been principally indebted to the celebrated Abelard, whose lectures are said to have been at one time attended by no fewer than three thousand scholars. At this period many new churches were also erected; two fortresses were built at the extremities of the bridges called Le Grand and Le Petit Châtelet; and the suburbs of the city were now for the first time enclosed by a wall. In the reign of Louis VII., which extended from 1137 to 1180, the first college properly so called was founded in Paris. Various other schools and religious institutions, and several hospitals, were also established about this time. But it is to Philip Augustus, the son of Louis VII., that Paris owes many of its chief ornaments. When that monarch ascended the throne, most of the churches and other public edifices were only of wood. He rebuilt many of them of stone, and added several new ones of the same material. He provided the different parts of the city with public fountains, paved the streets, and completely surrounded the city and suburbs with a new wall. During the reigns of Francis I. and his successor, additions were made to the public buildings upon a most extensive and magnificent scale, and the city increased with such rapidity that Henry II. deemed it necessary to restrain the continued augmentation of his capital, by issuing an edict prohibiting the erection of any more houses in the suburbs, on pain of confiscation of the land and buildings. This edict was repeated at different times by succeeding monarchs, but apparently without any effect. Paris suffered severely during the wars of the League, in consequence of the hostile assaults and other calamities to which it was exposed; and many of the public buildings and houses of the nobility were laid in ruins. But these marks of civil contention were speedily effaced on the ascension to the throne of Henry IV., who was the first to embellish the city with regular squares, decorated with the different orders of architecture. Several of the unaccomplished schemes of this prince were carried into effect by his successor, Louis XIII., in whose reign the palace of the Luxembourg was built by Maria de' Medicis, and the Palais Royal by the Cardinal de Richelieu, and the celebrated Jardin des Plantes was laid out on the opposite side of the river, towards the eastern extremity of the town. During the long reign of Louis XIV. Paris was embellished by the erection of a vast number of new and splendid buildings, both public and private, and was extended in all directions. The magnificent Hôtel des Invalides was erected at the western extremity of the Faubourg St Germain. Great additions were also made to the royal palaces of the Louvre and the Tuileries. The old ditches, from the standing water of which putrid and noxious effluvia constantly arose, were filled up; the ramparts were demolished, and the present Boulevards formed in their place; and two triumphal arches were substituted for the gates of St Martin and St Denis.

The reign of Louis XV. and his successor Louis XVI. witnessed a considerable extension of Paris in various directions. Several of the adjacent villages were joined to it, and formed new faubourgs; many improvements were made in the interior of the city; numerous schools, markets, and places of public amusement, were also erected. To the taste and energy of Napoleon, Paris owes many of its most magnificent embellishments. The improvements which he added to it in the short space of twelve years surpassed those of the three preceding reigns. These consisted of twenty-four new fountains, which served at once to adorn and purify the streets; the public granaries in the garden of the arsenal; the abatoirs, many new markets and quays, four spacious cemeteries, and the Canal of the Ourcq; besides the bridges of Arts, the City, Austerlitz, and Jena. Several splendid new streets and public edifices may also be mentioned amongst the works which were either commenced or completed during his sway. The fall of that extraordinary man interrupted for a time the embellishments of Paris; but after the restoration, some works which had long been projected or begun were after many interruptions continued, and, now that they are finished, they may vie with the most useful and splendid edifices of the capital.

Situat

Paris, as has been already stated, is built on a plain on both banks of the river Seine, which at this place flows in a direction nearly from south-west to north-east. The river, as it flows through the midst of the city, is interrupted in its course by three small islands, the two most westerly of which, the Ile de la Cité, and the Ile St Louis, are covered with buildings. The third, called the Ile Louvier, is used only as a dépôt for firewood. The parts of the city on the opposite sides of the river are connected with these islands and with each other by nineteen bridges, several of which are distinguished by their elegance or splendour, and add greatly to the beauty of the city. Throughout its whole length within the barriers, the banks of the Seine are skirted on both sides with spacious stone quays, furnished with parapets, and forming two broad and continuous streets between the water and the city. These quays, thirty-four in number, not only improve greatly the appearance of the river, but also furnish an important public accommodation. They are decorated with various buildings, both public and private, and they form one of the most pleasant walks in Paris.

Form
extent
the cit

Paris is nearly of a circular form. It consists of three divisions; the Ville, situated on the north, the University on the south, and the City in the centre. It stretches along the river about four miles and a half, and its breadth from the barrier St Denis to the barrier St Jacques is about three miles and a half. In the early part of the reign of Louis XVI. it was surrounded by a wall about seventeen miles in circumference, to prevent the introduction of contraband goods; but as this wall encloses a considerable space of ground which is uninhabited, and even under til-

Paris.

lage, the real extent of the city is very different from its apparent magnitude.

treets.

The impression which the general appearance of this metropolis is calculated to make upon a stranger is not of the most favourable kind. The streets in the more ancient parts, and in the centre of the city, are crooked, narrow, dark, and dirty. They are also extremely ill paved, and few of them even now possess any accommodation for foot passengers. The causeway itself is often most rugged and uneven, and is made to incline from both sides towards the centre, in order to form a run for a constant stream of black mire, there being no subterranean drains.

The general aspect of the French capital by night is singularly gloomy, so that it is almost impossible for the pedestrian to direct his steps aright. The lamps, instead of being fixed on posts at the sides of the streets, are suspended in the middle on ropes swung across, and having their opposite ends fastened to the walls of the houses. It was these ropes which the mob, in the first French Revolution, were wont to make use of as halters for their victims, and hence their well-known cry of *à la lanterne*, as they dragged them along to execution. Gas has, however, long been introduced into the shops and public buildings, and the whole city is expected in a short time to be lighted in the same manner.

Iouses.

The houses, which are generally constructed of stone, are often six or seven stories high. Their unusual height, the massive thickness of the walls, and their lower windows, which in many cases are strongly barricaded with iron, give to them an air of gloom and precaution more suited to a prison than a private dwelling. Like the buildings of the Scottish metropolis, they are inhabited by a great variety of families of all gradations of rank, from the nobleman, who occupies the first floor, to the milkman or cobler, who inhabits the garret. The whole of this motley community use the same magnificent staircase; and as the cleansing of it is the duty of no particular individual, it is often suffered to remain for months without being profaned by the mop or broom. Even when a hotel is inhabited by one family only, it is not unusual to make the upper story the receptacle for the hay and straw of the horses. Many of the larger houses do not present a simple front to the street, but only the side of one immense wing, or they are completely concealed by a high wall, erected so as to intercept the view from the street. Adjoining houses often form a complete contrast to each other in height, in workmanship, and in almost every other respect; and it not unfrequently happens that a mansion of the humblest sort, inhabited by the very meanest of the citizens, is situated beside a splendid edifice, the residence of one of the most opulent or most noble families of France.

ule-
rds.

To the general inelegance of the streets of Paris there are, however, several remarkable exceptions. The Faubourg St Germain, in particular, contains some of the finest streets in Europe. But perhaps the most spacious and extensive street of the French metropolis is the celebrated road called the Boulevards. The northern Boulevards are twelve in number, the southern seven. They may be generally described as a road or street of great breadth, along each side of which are planted double rows of elms. Those to the north of the river are lined on both sides, throughout their whole extent, by buildings of the most handsome description. Some of these are private residences; others are shops, cafés, public hotels, and theatres. These shady avenues present a striking picture of rural beauty combined with artificial elegance and splendour. The magnificence of the buildings, the majestic trees with which the place is adorned, the winding form and great breadth of the street, and the gay and festive crowds by whom it is frequented, give to the scene singular liveliness and brilliancy, and render the Boulevards one of the most interesting and splendid spectacles which any modern city can exhibit.

Paris.

According to MM. Bérand and Dufey (*Dictionnaire Historique de Paris*), the streets of Paris, supposing all their names counted, amounted, in 1828, to 1180, besides 120 *cul-de-sacs*, 158 passages, twenty-seven alleys, thirty-two cross-ways, and seventy-four *places* or squares. There were also ten cloisters, twenty-two courts, seven enclosures, and forty-seven market-places. The town was lighted in 1830 by 4533 lamps, having 10,672 burners, exclusively of 482 lamps belonging to public establishments.

The system of numbering the houses in Paris is much more uniform and perfect than that in the British capital; and there is a peculiarity in the manner which will often prove a useful guide to the stranger. The numbers begin with that part of the street which is nearest to the Seine, or at the east end when the street is parallel with the river. The even numbers are always arranged upon the right, and the odd numbers on the left side, of the street. The numbers of the houses, and the names of the streets which are parallel with the course of the Seine, are painted in red letters, but those which are perpendicular to the Seine are in black.

Public buildings.

It is universally allowed that Paris is superior to any other European metropolis in the number and magnificence of its public buildings. The palace of the Tuileries is of comparatively modern date, and therefore possesses none of those traditions of ancient feudal tyranny and magnificence by which the palaces of European capitals are generally distinguished. This edifice derives its name from having been erected on a piece of ground appropriated to the manufacture of tiles. It was founded by the infamous Catherine de' Medicis, when her former residence, the Palace Tournelles, was destroyed by Charles IX. The land and neighbouring houses were purchased by her at a considerable expense, and the building was proceeding with great rapidity, when she became alarmed by an astrological prediction, which bade her beware of St Germain; and the Tuileries being in the parish of St Germain l'Auxerrois, the completion of the sumptuous fabric was suddenly relinquished. The palace was much enlarged by Henry IV., and the works, suspended by his death, were carried on and terminated under Louis XIII. The architects Levau and D'Orbay were employed by Louis XIV. to complete the gallery, and to harmonize the discordant masses of this extensive range of building, erected at different periods, and exhibiting various orders of architecture, differing in height and in ornament. Since then, few additions have been made to the original building of the Tuileries, but considerable changes have taken place in others dependent upon them. The front now consists of five pavilions, comprising that in the centre, with four ranges of buildings connecting them together, and forming one grand façade. The general effect of the Tuileries is exceedingly imposing; more, however, from its great length and varied outline, than from any excellence of detail. The garden front is the best, and, though heavy, and incongruous when analysed by architectural taste, is unquestionably magnificent. The view of the garden from the portico is unrivalled as a scene of artificial beauty. The eye ranges over an immense parterre, bordered with orange trees, enriched with statues, diversified by fountains and shady groves, and crowded with a pleasure-loving population. The view is continued across the beautiful walks of the Elysian Fields for a distance of several miles, and is terminated by the triumphal arch of the Barrière de Neuilly, which crowns the summit of the hill. The gardens of the Tuileries are the work of Lenôtre, the celebrated gardener of Louis XIV. They have always been accounted the chief monuments of his genius; and, indeed, they are the finest specimens in the world of their peculiar style of disposition and embellishment. They are always open to the public, and are the most fashionable promenade of Paris, both in summer and in winter.

The palace of the Tuileries was the official residence of Napoleon, and since his days it has remained the chief abode of the reigning monarch.

On the side of the Seine, the celebrated gallery of the Louvre connects that palace with the Tuileries. Of the more ancient palace, which was surrounded by ditches and flanked by massive towers, there exist no remains. That part of the edifice now known by the name of the Old Louvre was begun under Francis I., but was first inhabited by Charles IX., whose memory is associated with this palace by the infamous deed of treachery and bloodthirsty bigotry which is known by the name of the massacre of St Bartholomew. The court of the Louvre forms a square about 400 feet in extent. The buildings which surround it, having been erected at different periods, vary materially in their style of architecture and ornaments.

The principal façade, commonly called the Colonnade of the Louvre, was finished in 1670 under Louis XIV. by the celebrated architect Claude Perrault, and is unquestionably a magnificent monument of genius. The central mass of the building, forming the gateway, is crowned by a pediment, the sloping stones of which are each in a single piece, fifty-two feet in length, and three feet in thickness. The folding gates in the centre, constructed by order of Napoleon, are of bronze, and are splendidly ornamented. The general appearance of this important and interesting edifice is indisputably grand and majestic; but the narrowness of the open space in front, and the mean buildings with which it is so immediately associated, weaken the impression which it is otherwise calculated to produce. Since the reign of Louis XV. the Louvre has been devoted to the reception of the various royal museums of the fine arts, which constitute some of the principal and peculiar attractions of the capital of France. It has occasionally been used also for solemn purposes of state. During the imperial government, the palace of the Louvre was considerably repaired and embellished; and since the restoration much has been done towards its completion. It still, however, remains unfinished, in many places wanting windows, and being for the most part destitute of interior ornaments.

The Palais Royal was built by the celebrated Cardinal Richelieu, who, at his death, bequeathed it to Louis XIII. In 1692, Louis XIV. gave it to his nephew Philip of Orleans. At the time of the Revolution it was the residence of the infamous Duke of Orleans, better known by the name of Egalité, to whom it is indebted for much of its present magnificence. Having exhausted his noble revenues by a course of luxury and profligacy almost unparalleled, he determined, in order to save himself from ruin, to convert his splendid residence into an immense bazaar. The beautiful arcades of the lower galleries were divided by diminutive and ill-executed pilasters, and the garden was surrounded by a row of little shops, which were speedily let to the highest bidder. A few of the upper galleries were appropriated to the lectures of various professors, and to the meetings of literary and scientific societies; others were let to restaurateurs, but more were devoted to the accommodation of the gambler and the sensualist, and became the favourite haunt of every species of vice and debauchery. The Palais Royal has been called, not without some reason, the capital of Paris. It is certainly entered both by inhabitants and strangers more frequently than any other spot of equal dimensions in the city; and it is the perpetual rendezvous of all the idle and worthless in the capital. His present majesty, when Duke of Orleans, resided in this palace (with the exception of the interval of the "hundred days") from 1814 till 1831, making some additions and improvements in various parts of the structure, and fitting up the whole anew. At present it serves for the accommodation of foreign princes during their residence in Paris.

The palace of the Luxembourg, one of the apartments of which now forms the Chamber of Peers, is an edifice remarkable for the beauty of its proportions, and for the character of strength and solidity which it at the same time possesses. It is a square building, with an ample portico in the centre. The front consists of two large pavilions, connected together by terraces, supported by open galleries, in the centre of which rises an elegant cupola surrounded with statues. Its interior contains a splendid gallery of modern paintings.

The Palais d'Elysée Bourbon, an edifice remarkable for its luxurious elegance, was the favourite residence of Napoleon. It was to this palace that he returned after the battle of Waterloo; and here was performed the closing scene of the hurried drama of the "hundred days." After the final departure of Napoleon it was inhabited by the Duke of Wellington. It was afterwards the residence of the Duke de Berri, and on his assassination it was appropriated to the Duke de Bordeaux. It now belongs to the crown. The interesting associations connected with this small palace render it one of the most valuable public monuments of Paris.

Church

Before the Revolution, Paris contained one hundred and sixty Catholic churches or chapels. At present it does not contain more than thirty-eight, namely, twelve parish churches and twenty-six chapels of ease, thirty-five convents for women, and as many monastic seminaries. Six chapels belong to different sects, viz. three to Calvinists, one to those of the Augsburg Confession, one to the eastern Christians, and one to the Jews.

The two most important churches which the French capital exhibits are those of Nôtre Dame and the Pantheon or church of St Geneviève. The cathedral of Nôtre Dame, the mother-church of France, is a vast and magnificent building of the Gothic order, and is the most ancient religious edifice in Paris. It is 414 feet in length, 144 in width, and 102 in height, without comprehending the space allotted to forty-five chapels, and the astonishing thickness of the walls. One hundred and twenty enormous columns, which support this edifice, form a double colonnade extending the whole length of the fabric; and 297 columns, each cut from a single block, are distributed in various parts of the building. This magnificent structure is so old that the precise date of its original foundation is unknown; and its massy and venerable appearance presents a striking contrast to the modern buildings with which the city is filled.

The Pantheon, or church of St Geneviève, is perhaps the most magnificent of the modern edifices in Paris. The plan of the building is a Greek cross, forming naves which unite in a centre, surmounted by a dome of vast dimensions, which, being the highest object in Paris, is visible from any part of the city. The west portico bears some resemblance to the Pantheon at Rome, and is composed of twenty-two fluted Corinthian columns sixty feet in height and six in diameter, which support a triangular pediment a hundred and twenty feet in breadth by twenty-four in height. The pediment is now receiving some sculptures by David; and, on the frize beneath it, is the following inscription, in reference to the vaults beneath the church being used as a place of sepulture for illustrious characters:

Aux grands hommes la patrie reconnaissante.

Amongst the distinguished personages interred here are Voltaire, Rousseau, the mathematician Lagrange, Bougainville the navigator, Marshal Lannes, and the Dutch admiral De Winter. Of the other churches of Paris, those of St Sulpice, St Eustache, and St Roche, are the only ones which deserve to be particularly noticed for their size and elegance.

Paris.

The clergy of Paris are composed of one archbishop, two vicars-general appointed by the king, and nine others; three secretaries, one penitentiary, three metropolitan officials, four diocesan officials, and sixteen canons of Nôtre Dame, the first of whom is archdeacon; thirty-four honorary canons, two masters of the choristers, five superintendents of the edifice of Nôtre Dame, and three superiors of seminaries. To these must be added the curates and officiating ministers of the churches of Paris, of whom there is one to each church. The number of vicars is not accurately known, and there is also an indefinite number of almoners of hospitals, convents, and other establishments.

The total number of the Catholic clergy in France is about 41,298, including four cardinals, fourteen archbishops, and sixty-six bishops. To these may be added 10,904 theological students intended for the priesthood. The number of convents for nuns of different orders is about 3000, and the number of nuns about 24,000. There are also in France a few establishments of monks of La Trappe, and one of Carthusians or Chartreux. Of the ministers of other religious denominations there are, Lutherans, 388; reformists of the Confession of Augsburg, 345; Jews, eight; and of other denominations, eighty-six. The total expense to the state, of all religions, is 34,289,000 francs, or L.1,371,560. At the time of the Revolution the total number of ecclesiastics was 114,000, including 19,000 regular clergy, and 32,000 nuns of all orders. Their annual revenue amounted to seventy-two millions of francs, and the tithe to seventy millions, giving a total of 142 millions, or L.5,680,000 sterling.

emete-es.

The Parisians formerly buried their dead in the Roman fashion, without the city walls, along the sides of the high roads. But the increase of the population rendering it necessary to extend the bounds of the city, the cemeteries became in the process of time enclosed within the walls, and at length were almost in the heart of the town. They were so few in number, and so confined in space, that the inhabitants were thereby compelled to adopt a mode of burial altogether revolting to decency and humanity. Vast trenches were opened, into which corpse after corpse was deposited, until the putrid heap nearly reached the surface of the ground. The earth was then thrown over them, and similar trenches dug close by their side. As might have been expected, the neighbourhood of these cemeteries became proverbially the seat of every pestilential disease, till at length government interfered and prohibited all burials within the city, and ordered three cemeteries to be enclosed for the use of Paris, at a distance of about one mile from the walls. The cemeteries of Paris are now five in number. They are laid out in a picturesque style; the monuments are often in good taste, and the inscriptions are interesting. The cemetery of Père la Chaise, in particular, is one of the most beautiful as well as interesting sights of Paris. The advantageous situation of this spot upon the slope of a hill, surrounded by luxuriant valleys and rising grounds, and commanding an extensive view of a picturesque and glowing landscape, has occasioned its being chosen by the most distinguished personages as the place of their interment; and hence no Parisian cemetery can vie with that of Père la Chaise in the number and beauty of its monuments.

acombs.

In 1784, the council of state issued a decree for clearing the cemetery of the Innocents, and for removing its contents, as well as those of other cemeteries, and converting their sites into squares or market-places. The bones being separated, and carefully cleaned, were piled in some of the immense galleries of the quarries by which a great part of the city is undermined; and the name of the Catacombs was given to this new receptacle of the dead, in imitation of similar excavations appropriated to the same purpose in Rome, in Milan, in Naples, and in ancient Thebes. The calculations differ as to the number of bones collected in this vast charnel-house. It is certain, however, that it contains the remains of at least three millions of human beings.

Literary institutions.

The metropolis of France is extremely rich in literary and scientific institutions, not a few of which have obtained great celebrity. The National Institute or Royal Society is the most distinguished of these learned societies. The great reputation of this institution, and the obligations which it has conferred both on French and European science and literature, are universally acknowledged. It was established during the reign of Louis XIV. and is composed of the most distinguished philosophers, literary characters, and artists of France, and maintains a correspondence with the learned of every nation. It is divided into four classes, which may be considered as forming so many distinct societies. Each class has its separate meetings, but four times in every year the whole society assembles, and a general report is made of the labours and progress of the institution. The first division is devoted to natural philosophy, chemistry, and mathematics; the second to French literature and the French language; the third to history and ancient literature; and the fourth to the fine arts. The public meetings of the National Institute are held in a very extensive and magnificent apartment, adorned with marble statues of the most celebrated persons whom France has produced. The society of the Bureau des Longitudes is engaged in constant astronomical observations at the Observatory and in the Military School; and for this purpose it has at its disposal all the astronomical instruments belonging to government. It corresponds with the other observatories of France, and with those of foreign countries, and suggests to the government where it is desirable to establish observatories.

Seminaries.

The University of France is indebted for its origin to the illustrious Charlemagne, and has for centuries been celebrated throughout Europe. It was suppressed in 1792, but afterwards re-established on a more extensive and liberal plan. The superintendence of the business of education throughout France is now intrusted to a council, under the Minister of Public Instruction, and no school or place of instruction can be established without their permission. The university possesses a library, which is placed at the Sorbonne, and special funds are provided for granting pensions to superannuated and infirm teachers. There are many other establishments in Paris of a similar description. Of these, perhaps the most celebrated is the Royal College of France, in which there are twenty-three professors who give public and gratuitous lectures in every department of science and literature. In addition to the colleges, there are a great number of schools for special purposes founded in Paris, mostly by the government. At the head of these stands the Polytechnic School. The object of this most useful and justly celebrated institution is to diffuse the knowledge of the mathematical, physical, and chemical sciences, and to form pupils for the artillery, engineering, and other departments, into which no officer can be admitted who has not been educated in this school. The most distinguished masters in every branch of science are employed by the government. Every year a certain number of scholars are admitted, after undergoing the most rigorous examination in the classics, the mathematics, mechanics, and drawing. The number of pupils amount to three hundred. The period usually allowed for study is two years, but in certain cases it is extended to three. The school possesses an excellent philosophical and chemical apparatus, and a well-selected library, consisting of 24,000 volumes. The pupils of this establishment took a prominent part in the Revolution of 1830. In the School of Bridges and Roads, eighty pupils selected from the Polytechnic School are taught every branch of science connected with the construction of bridges, canals, harbours, roads, and public

Paris.

edifices. The museum contains a noble collection of plans, charts, and models. There is also an academy, termed the School of the Fine Arts, appropriated to the teaching of painting, sculpture, and architecture, in which lectures are given gratuitously, on every subject connected with the fine arts, by twenty professors. Besides, Paris possesses several great public schools devoted to elementary instruction; and every year is bringing improvements to this most important branch of national education. There are also many private academies; and, altogether, the institutions appropriated to the instruction of youth in the French capital are in a most flourishing condition.

Libraries.

Extensive and valuable collections of books are attached to almost every public institution and every public building in Paris. The most splendid of these collections is the Royal Library, which is justly considered as the largest and most valuable in Europe. It contains no fewer than 900,000 books and printed pamphlets, 80,000 manuscripts, 1,600,000 engravings, 300,000 maps and plans, and a most valuable collection of medals and antiquities. With a liberality highly honourable to the French character, people of every class and rank, as well as strangers from any quarter of the globe, are allowed access to it, and every necessary accommodation is provided for their use. Of the other libraries, which are extremely numerous, those of the arsenal, the Pantheon, and the Institute, are the largest and most important, and the greater part of them are open both to the Parisians and to strangers. (See the article LIBRARIES, vol. xiii. p. 285.)

Museums.

The collections of works of art, and of subjects connected with natural history, with which Paris abounds, ought not to be passed over in silence. The Museum of the Louvre, during the sway of Napoleon, was the boast of Paris, and contained almost every celebrated work of art that could be procured on the continent of Europe. On the downfall of this extraordinary man, a portion of these treasures were restored to their rightful owners; but the collection, even as it now stands, is unrivalled. The walls of the Louvre are still covered with a fine collection of pictures and statues from the Luxembourg, Versailles, and other royal residences, and partly from private collections. The paintings also which adorned the numerous churches destroyed during the frenzy of the Revolution have found an asylum in this interesting and valuable museum. The great gallery of paintings is a most magnificent apartment, 1400 feet in length, and contains upwards of 1400 pictures of the most eminent masters of every school.

Few museums are more interesting, instructive, or valuable, than the Conservatory of Arts and Trades, an immense repository of machines, models, and drawings, for the improvement of machinery and implements connected with manufactures, agriculture, and other branches of industry. It is a collection peculiar and highly creditable to the metropolis of France, and has undoubtedly been productive of the most beneficial effects in diffusing an extensive knowledge of mechanics, and a skilful adaptation of the simplest instruments to the most complicated purposes. The Museum of Artillery is a repository of every kind of warlike instrument. It likewise contains a valuable collection of the different kinds of armour used in every period of French history. The Museum of Natural History in the Jardin des Plantes stands at the head of all institutions of the kind, not only in France, but in the world. The name of Jardin des Plantes expresses very inadequately the real nature of the institution; for, in addition to a noble botanic garden, it contains a large menagerie, a museum of natural history and anatomy, and numerous halls in which public lectures are delivered on every branch of natural history and philosophy. This garden was founded by Jean de la Brosse, physician to Louis XIII.; but it is principally indebted for its present beauty and value to the assiduous labours of Buffon. From the commencement of the Revolution until the time of Napoleon, the institution was greatly neglected and abused for want of funds. But on his arriving at the head of affairs a new impulse was given to the establishment, and the only temporary check which it received was on the occupation of Paris by the allies, when a body of Prussians were about to take up their quarters in the garden; but the spirited remonstrances of the celebrated traveller Humboldt obtained a safeguard for the museum, and an exemption from all military requisitions. There was great reason to fear that the museum would be deprived of some of the valuable parts of its contents, by the restitution of the treasures which had been plundered from neighbouring countries. In fact, the magnificent cabinet of the stadtholder was reclaimed; but it was afterwards agreed that an equivalent should be furnished from the duplicates of the museum. An arrangement equally friendly and equitable was effected respecting the minerals and zoological specimens which had been taken from the Austrian dominions in Italy. Since that time the support of this museum has been munificently provided for by the state, and its condition was never so flourishing as at the present moment. Its collections of every kind are equally valuable and rare. The garden and the menagerie contain specimens of almost every living production of the animal or the vegetable kingdom, arranged with great taste and skill. For the cabinet of comparative anatomy, incomparably the richest in existence, the museum is indebted to the unwearied exertions of Baron Cuvier, by whom it was arranged, and under whose direction most of the objects were prepared. The cabinet of natural history is equally precious, and still more complete. In the zoological and fossil departments it is unrivalled; and one of the halls contains some interesting specimens of the animal remains of the antediluvian world, with the skeletons of numerous animals now unknown or extinct. There are various other institutions of a similar kind in Paris, of which the Royal Museum at the Luxembourg, and the Cabinets of Mineralogy and Anatomy, are the most extensive and celebrated.

Monuments.

Of the public monuments the greatest is the column in the Place Vendome, erected under the superintendence of Denon, in commemoration of the campaign of 1805, upon the model of Trajan's Pillar at Rome. It is 134 feet high by twelve feet in diameter, formed of the metal of 425 brass cannon taken from the Austrians and Prussians in that campaign. It was originally surmounted by the statue of Napoleon, which was removed in 1814, and replaced in 1831. The triumphal arch in the Place du Carousel, built on the plan of that of Septimius Severus at Rome, is not inferior to its celebrated original. In 1806 a triumphal arch of surpassing magnitude was commenced at the extremity of the principal avenue of the Champs Elysées; but after it had attained a considerable elevation it was stopped by the reverses of the Russian campaign. Our limited space forbids our describing other monuments highly deserving of notice, such as the gate of St Denis, the gate of St Martin, the equestrian statue of Henry IV., the obelisk on the heights of Chaillot, &c.

Hospit

The hospitals and charitable institutions of Paris are remarkably numerous and extensive. They are supported and maintained by government, and are under the direction of a general council and an administrative committee, consisting of some of the most distinguished functionaries of the state, the principal magistrates, and others remarkable for their talents and philanthropy.[1] According to the report published by the prefect of the department in 1834, the hospitals, thirteen in number, contained 5337 beds, and the hospices, eleven in number, 11,740 beds, giving a total of 17,077 beds. The number of patients in the hospitals on the 1st of January 1833 was 4170, in the hospices 9567; and the number admitted during the year was, in the former 61,765, in the latter 3190; giving a total in hospitals and hospices for 1833 of 78,692. On the first of January of the same year, there were supported by the hospices 17,433 foundlings and orphans; and to these were added during the year 5693 foundlings, whilst 1760 children were placed out gratuitously to nurse, and 68,986 persons were relieved at home by the Bureau de Bienfaisance; thus giving a general total of persons supported and assisted by public charity during that year, of 172,564. The proportion of the number of indigent persons in Paris to that of the whole population is as one to eleven; and the number of the indigent families relieved was 31,723. According to the same account, the total expenditure, in 1833, of the hospitals and charitable institutions dependent on them was 10,186,388 francs. The mean time of a patient's remaining in the hospital was twenty-three days, and the average cost of each patient was thirty-eight francs. The number of deaths in the hospitals was 5886, giving a mean mortality of one in eleven. In the hospices, the cost of each patient per day was eighteen sous, the number of deaths 1548, and the mean mortality about one in six. The number of the foundlings was 23,126, and the cost of supporting each was seventy-four francs. There is a board of medical men, called the Bureau Central d'Admission, established for the inspection of persons desiring to be admitted into the hospitals when the case is not one of urgency. The particular hospital is indicated by this board to the patient, according to the nature of the complaint; and no one can be admitted into any without an order from its members.

---

[1] The name of Hospitals is generally appropriated to the establishments for the sick, and that of Hospices to those in which children and the aged and infirm are received.

At the head of the charitable institutions of Paris stands the Hôtel des Invalides. This magnificent edifice, which has been termed the Chelsea Hospital of France, was erected by Louis XIV. for the reception and maintenance of disabled and superannuated soldiers. The buildings are very extensive, and, with the adjoining grounds, which are tastefully adorned with long alleys of trees, cover a space of nearly seventeen acres.

This excellent institution is under the direction of the minister of war. The governor is a marshal of France; and under him there are a lieutenant-general, commandant of the hotel, and a colonel called colonel-major. The establishment is capable of containing 7000 persons, but at present there are not above 3500 in it; and even this number is likely to be considerably diminished, in consequence of the long continuance of peace. Skilful physicians are attached to it, and the Sisters of Charity nurse the sick with the greatest care. These old warriors find in this asylum abundant and wholesome food, every attention to their infirmities and wounds, and pay proportioned to the rank they held in the army. The officers and privates have separate refectories, and those above the rank of captain dine in their own rooms. They all wear the same uniform, and whenever the king comes within their walls they have the exclusive privilege of guarding his person. Their only duty is to mount guard at the hôtel and its dependencies. The interior was embellished by cannon taken at various periods by the armies of France. A considerable number of banners are ranged along both sides of the nave of the church. They are mostly Spanish and Portuguese; but amongst them there is a large collection of Algerine standards, all won on the field of battle. In the time of Napoleon nearly 3000 flags filled the nave; but on the evening before the entry of the allied armies into Paris in 1814, the Duke de Feltre, minister of war, by order of Joseph Bonaparte, commanded them to be burned, that they might not fall into the hands of the enemy.

The Hôtel Dieu, which is the oldest hospital in Paris, is unfortunately situated in the most populous part of the city. It was formerly very crowded and inconvenient, but has received great improvements since the Revolution. It comprises at present twelve wards for men and eleven for women, containing altogether 1260 beds. There are many other institutions in Paris of a charitable and benevolent nature, which are all conducted on the most liberal principles, and of late years they have undergone very considerable improvements.

Savings' Bank.

There is also an excellent institution called the Caisse d'Epergne et de Prevoyance, intended as a kind of savings' bank, which deserves to be noticed for the important benefits it has conferred upon the industrious classes. The administration is gratuitous, being defrayed out of money with which it was endowed by the original founder. Deposits of from one to fifty francs are received, and four per cent. compound interest is allowed on them. Not more than 2000 francs can be kept by any individual in this bank, and the whole or part of the deposits may be withdrawn on giving five days' notice. The total amount of money paid into the establishment during the year 1835 was 24,085,174 francs, divided amongst 150,000 depositors. It is gratifying to learn, that the importance and utility of this most benevolent institution are extending every year.

Courts.

The Minister of Justice is the supreme head of all the courts in the kingdom, and keeper of the seals. To him belongs the organization and superintendence of the whole judicial system, and of the body of notaries.

The courts of justice in France are now comprehended under three grand divisions, viz. the Tribunaux de Première Instance, the Cours Royales, and the Cour de Cassation. There are, besides, several special courts, such as the Tribunaux de Commerce, the Cour de Comptes, and the Officialités or Ecclesiastical Courts.

The Cour de Cassation, which is held in the Palais de Justice, is the supreme court of appeal from all the tribunals of France. It can alter the decisions or judgments of any court or tribunal, and there is no appeal from its decrees. It can censure the royal courts, summon the judges to render an account of their conduct, and even suspend them from the exercise of their functions. The Court of Cassation is composed of a president, three vice-presidents, and forty-five councillors, nominated for life by the king, and is divided into three sections, called sections of requests, and of civil and criminal cassation.

The Cour des Comptes, or Court of Exchequer, is the court next in rank to that of Cassation, and enjoys the same prerogatives. It takes cognizance of all matters relating to the revenue, and examines all the principal accounts of the kingdom. For the despatch of business it is divided into three sections or chambers, each of which has a president and six conseillers-maîtres.

The Cour Royale consists of a president, five vice-presidents, and numerous other officers. It is divided into five chambers; three for civil actions, one for appeals from the correctional police, and another for accusations or indictments.

The Tribunal de Première Instance is divided into eight chambers; five for civil affairs, and the others for affairs of the correctional police, and all offences relative to the customs, indirect taxes, excise, &c.

The judges of the Tribunal of Commerce are respectable merchants, principally heads of ancient houses, who are nominated in a general assembly of merchants, subject to the approbation of the king.

The order of advocates is very numerous, and justly celebrated for their talent and learning. They have a bureau

Paris.

for gratuitous advice to the poor, at their library in the Palais de Justice.

The number of notaries in Paris who exercise their profession within the jurisdiction of the Royal Court is 114. They give security to the government, and on their retirement or death their places are sold.

Municipal government and police.

The chief officer of the municipality of Paris is the prefect of the Seine, who may be said to exercise the functions both of what we should call lord-lieutenant of the county or department, and of mayor of the city. Under him is a council of prefecture, composed of five members, and also a secretary-general. The council-general of the department consists of forty-four members, three of whom are elected by each arrondissement of Paris, and four by each rural arrondissement. Each of the twelve arrondissements into which the city is divided has its particular municipality, presided over by a mayor and a justice of the peace, and four commissaries of police, one for each of its quarters. Besides the prefect of the department, who resides at the Hôtel de Ville, there is also the prefect of police, whose residence is in the Ile de la Cité, and who exercises his authority in subordination to the minister of the interior. The police of Paris has been brought to a state of great perfection, and such is the immense number of clerks, officers, and spies employed, and so strict is the system of espionage, that they possess the most minute information respecting the character and pursuits of every suspected person; indeed their secret agents, chosen from all classes of society, and paid accordingly, are to be found in almost every public assembly.

Prisons.

The prisons of Paris were at one time as wretched in their accommodations, and as unhealthy, as those of any city in Europe. Immediately before the Revolution, considerable progress was made in improving them; but in 1795, the National Convention ordered a report to be drawn up respecting the state of the prisons; and in the following year a criminal and penal code was formed, which fixed with greater precision the competency of the different tribunals, and separate prisons were appointed for the different classes of offenders. The changes effected in the criminal legislation since the Revolution have necessarily produced a great improvement in the prison regulations; and the new buildings lately erected for such purposes promise to produce the most beneficial results, not only to the prisoners, but also to the community at large. The prisons existing in Paris are now eight in number, and the persons confined in them are divided into the following classes; those under accusation, debt, or political offenders, and offenders liable to only one year's imprisonment; persons under trial, persons condemned to hard labour, juvenile criminals, and females; all of which are under the jurisdiction of the prefect of police. Besides, there are three military prisons, under the jurisdiction of the minister of war.

Trade and manufactures.

Commerce and manufactures have by no means attained that degree of prosperity which we might be led to expect from the size, population, and facilities of the city. The staple manufactures of the French capital consist chiefly of articles of taste, and all kinds of fancy works, such as jewellery, watches, artificial flowers, toys, and the like. There are no authentic returns published of the produce of the different manufactures of Paris, calculated to the present day. An immense increase has, however, taken place within the last ten years, and is still proceeding very rapidly. The prefect of the department, in his report of 1834, estimates the manufactures of Paris exported to foreign countries at eighty millions of francs annually, and those for the consumption of the departments at the same amount. Of the manufacturing establishments of Paris, two belong to the government; namely, those for tapestry and carpets, and for snuff. The first of these, known by the name of the Gobelins, from a dyer who instituted it about the middle of the sixteenth century, manufactures that beautiful tapestry, the reputation of which has spread over all Europe. The principal subjects on which the looms are employed are copies of the most celebrated pictures of the French and Italian schools; for brilliancy of colour, fidelity of outline, and delicacy of execution, their productions are often little inferior to the most masterly touches of the pencil. Of the other manufactures of the capital, paper-hangings, leather, jewellery, chemical products, gas, fine hardware, fans, &c. give occupation to a vast number of persons, and yield considerable profits. Printing, engraving, and the preparation of all substances and materials connected with the fine arts, form very extensive branches of trade.

As every thing which enters Paris must be introduced by the Barriers, where duties are levied upon almost all descriptions of necessaries as well as luxuries, the quantities of the different articles of consumption used by the population every year are ascertained with extraordinary exactness. The following is a table of the consumption of the town of Paris during the year 1834, extracted from the *Annuaire du Bureau des Longitudes*.

Wine	877,769	hectolitres.
Brandy	35,716	...
Cider and perry	16,390	...
Vinegar	19,275	...
Beer	120,552	...
Grapes	1,569,356	kilogrammes.
Oxen	72,474	head.
Cows	14,175	...
Calves	70,739	...
Sheep	364,409	...
Pigs	85,336	...
Pies, preserved meats, &c.	1,122,466	kilogrammes.
Meat, coarse	2,553,422	...
Sausages, hams, salt pork, &c.	643,495	...
Offal	1,062,873	...
Cheese, dry	1,150,187	...
Sea-fish	4,229,388	francs.
Oysters	1,118,971	...
Fresh-water fish	307,949	...
Poultry and game	7,728,041	...
Butter	10,301,762	...
Eggs	4,441,384	...

The ordinary consumption of Paris in grain and flour is estimated at 158 sacks, each weighing 139 kilogrammes, daily, or 91,695,300 kilogrammes annually. The price of the loaf of household bread, of four pounds weight, varies from eleven to twelve sous. The annual consumption of potatoes in Paris is nearly 325,000 kilogrammes, or about 650,000 pounds. More than twenty cart loads of water-cresses are brought into Paris daily, each of which produces 300 francs, thus giving a daily consumption of 6000 francs for this article alone.

Taxes.

Indirect taxes produce on an average nineteen millions a year. The post-office collects annually in Paris alone about four millions and a quarter. The direct taxes amounted, in the year 1815, to about twenty-two millions; but at present they amount to twenty-eight millions. The revenues of the city of Paris for the year 1835 were 44,436,797 francs, and the expenditure for the same year was about 41,087,091 francs. During the year 1835 the sum of 6,286,000 francs was devoted by the municipality to the embellishment of the town; a similar sum of 6,615,000 francs was allotted to the same purpose for the year 1836; and the budget of the town for the year 1835 was expected to give a clear excess of 4,782,004 francs, to be devoted to improvements and embellishments. The total territorial revenue of the Seine, in 1835, amounted to about 54,418,000 francs. The produce of the octroi duties has been gradually increasing for some time past; in 1834 it amounted to 27,684,000 francs, and in 1835 to 29,050,000 francs. The average annual duties paid for the navigation of the Seine amount to about 700,000 francs.

The following are the official returns of the population of Paris.

	1789.	1801.	1811.	1821.	1831.	1836.
Paris	524,186	546,856	622,636	713,966	774,338	909,126
Saint-Denis	5,330	4,425	6,500	8,236	9,686	9,352
Sceaux	1,000	1,404	1,500	1,349	1,459	1,670
Total	530,516	552,685	630,636	723,551	785,483	920,148

The above numbers are exclusive of strangers and troops, which are never comprehended in these returns.

In the department of the Seine the numbers in 1836 were 1,106,891.

	Men.				Women.			
	Children and Unmarried.	Married Men.	Widowers.	Total.	Children and Unmarried.	Married Women.	Widows.	Total.
Paris	268,933	174,080	16,513	459,526	223,080	172,895	53,625	449,600
Saint Denis	28,026	23,804	2,419	54,249	26,244	23,672	5,892	55,808
Sceaux	25,904	17,967	1,739	45,610	19,670	17,863	4,565	42,098

All ranks of the inhabitants are distinguished by gay and agreeable dispositions, and great civility of manners. The polished character of Parisian society throws a veil of external decency over the more disgusting features of immorality. The eyes and the ears are not offended, as in London or Edinburgh, with the rudeness and blackguardism of vice; but the statistics of Paris indicate that, under the thin covering of superficial decency and civility, there lies a deep substratum of criminality and corruption.

The number of suicides in Paris is very great; on the other hand, the executions are few. These were, in

	1827.	1828.	1829.	1830.	1831.	1832.	1833.	1834.	1835.
Suicides	261	279	307	269	359	369	325	360	394
Executions	3	1	6	1	1	1	2	0	4

being an average of suicides of rather more than 346 for the last six years; whilst the capital punishments for the same period are on an average one and a half annually.

The laws for licensing and regulating female licentiousness, so far from checking the progress of corruption, seem rather to foster it. Every prostitute is compelled to take out a license at the proper bureau, for which she pays a stipulated sum. Her name, her age, and her abode, are entered in the books of the police; and once in every month she is visited by a medical man appointed for the purpose, who gives her, or withholds, according to circumstances, a *carte de santé*, or bill of health. Should she dare to pursue her calling without this license and this medical certificate, she is liable to fine, imprisonment, and corporal punishment. Some notion of the actual number of these females in Paris may be formed from the following table of the number of inscriptions during twenty years, which is abridged from the work of M. Perent Duchâtelet, whose benevolent exertions to prevent and restrain this frightful social evil deserve the warmest gratitude of all who are sincerely concerned in the welfare and improvement of the human race.

	Annual Total.	Monthly Average.
1813	20,113	1676·08
1815	22,249	1854·08
1820	32,957	2746·41
1825	31,483	2623·58
1826	29,948	2495·66
1827	29,663	2471·91
1828	31,956	2663·00
1829	34,118	2843·16
1830	36,337	3028·08
1831	39,128	3260·66
1832	42,699	3558·25

It thus appears that in 1832 the total number of females inscribed or registered as public prostitutes amounted to above 42,000, and the average monthly inscriptions were above 3500. As the population of the French metropolis was at the period referred to upwards of 800,000, the estimate now given makes the number of public females spending their lives in and subsisting by prostitution to be rather more than one in twenty of the whole population.

In 1834, the total number of births was 29,104, deaths 23,015, marriages 8091. Of the 29,104 births, 9985 were illegitimate, and of these, 4523 took place in hospitals and public institutions, and 3649 were recognised by the fathers. 14,023 persons died at their own houses, 7759 in civil hospitals, 895 in military hospitals, fifty in prisons, and 288 were deposited at the Morgue.[1] In the returns of the population of Paris for 1835, the births were,

	Boys.	Girls.	Total.
Legitimate	12,725	12,056	24,781
Illegitimate	5,476	5,297	10,773

Marriages 581. Deaths, males 15,519, females 14,587; deposited at the Morgue, males 226, females, forty-two; total 30,332. Of the foundlings who are every year received into the hospitals, above twenty per cent. die annually. According to the experience of a century and a half, the months in which the greatest mortality prevails in Paris are March and April, and the least August and July. The greatest number of children are born in March and January, the smallest in June, November, and December. The greatest number of marriages take place in May, the smallest in March and January. The number of male births exceeds that of females, on the average of the last seventy-seven years, in the proportion of nearly twenty-six to twenty-five. For the whole of France, the proportion is sixteen males to fifteen

females in the case of legitimate children, and as twenty-three to twenty-two for illegitimate children. Of the population of Paris, it has been calculated that nearly one half are working and labouring people, the rest being occupied in some trade or profession, or living upon their income. There are 80,000 servants, and nearly the same number of paupers. Nearly 15,000 patients are always in the hospitals, and about four times that number pass through the hospitals in the course of the year. There are about 20,000 foundling children supported by the state, and nearly the same number of aged and infirm incapable of working. The population of the prisons is generally about 4000.

---

[1] The Morgue is a small building where unknown and unclaimed corpses found by the police are left to be recognised by their friends. A window is constructed so as to enable those who look through it to see distinctly the bodies deposited in it; and it rarely happens that the passenger who turns aside to look will not be shocked with the view of one or more corpses on the floor.

Paris, *Matthew*, one of our best historians, but of whose life few particulars have been transmitted to us. Leland, his original biographer, without determining whether he was born in France or in England, informs us that he was a monk of St Alban's, and that he was sent by Pope Innocent to reform the monks of the convent at Holm in Norway. Bishop Bale, the next in point of time, adds, that, on account of his extraordinary gifts of body and mind, he was much esteemed, particularly by Henry III., who commanded him to write the history of his reign. Fuller represents him as a native of Cambridgeshire, because there was an ancient family of his name in that county, and also mentions his being sent by the pope to visit the monks in the diocese of Norwich. Bishop Tanner, Bishop Nicholson, Doctor Dupin, and the *Nouveau Dictionnaire Historique*, add not a single fact to those we have just related. Matthew Paris died in the monastery of St Alban's in the year 1259. He was doubtless a man of extraordinary knowledge for the thirteenth century; possessing an excellent moral character, and, as an historian, exhibiting strict integrity. His style is unpolished; but that defect is sufficiently atoned for by the honest freedom with which he relates the truth, regardless of the dignity or sanctity of the persons concerned. His works are, 1. Historia ab Adamo ad Conquestum Angliæ, lib. i. manuscript, col. C. C. Cantab. c. ix. Most of this book is transcribed, by Matthew of Westminster, into the first part of his *Florilegium*. 2. Historia Major, seu Rerum Anglicanarum Historia a Gul. Conquestoris adventu ad annum 43 Henrici III., several times printed. The first part of this history, viz. to the year 1235, is transcribed almost verbatim from the Chronicle of Roger Wendover; and the appendix, from the year 1260, is the work of William Rashinger, who was also a monk of St Alban's. 3. Vitæ Duorum Offarum, Merciæ regum, S. Albani fundatorum. 4. Gesta xxii. Abbatum S. Albani. 5. Additamenta Chronicorum ad Historiam Majorem. 6. Historia Minor, sive Epitome Majoris Historiæ, in manuscript. Paris left several works in manuscript.

Paris, the son of Priam, king of Troy, by Hecuba, and also named *Alexander*. He was decreed, even before his birth, to become the ruin of his country; and when his mother, in the first months of her pregnancy, had dreamed that she should bring forth a torch which would set fire to her palace, the soothsayers foretold the calamities which were to be expected from the imprudence of her future son, and which would end in the ruin of Troy. Priam, to prevent so great and so alarming an evil, commanded his slave Archelaus to destroy the child as soon as he was born. But the slave, either touched with humanity, or influenced by Hecuba, did not obey, and was satisfied with exposing the child upon Mount Ida, where the shepherds of the place found him, and educated him as their own. Some attribute the preservation of his life, before he was found by the shepherds, to the motherly tenderness of a she-bear, who suckled him. Paris, though educated amongst shepherds and peasants, gave very early proofs of courage and intrepidity; and from his care in protecting the flocks of Mount Ida from the rapacity of the wild beasts, he was named the "helper or defender." He gained the esteem of all the shepherds; whilst his graceful countenance and manly deportment recommended him to the favours of Œnone, a nymph of Ida, whom he married, and with whom he lived in the most perfect tenderness. Their conjugal peace, however, was not of long duration. At the marriage of Peleus and Thetis, the goddess of discord, who had not been invited to partake of the entertainment, showed her displeasure by throwing into the assembly of the gods who were at the celebration of the nuptials, a golden apple, on which were written the words *Detur pulchriori*. All the goddesses claimed it as their own, and the contention at first became general; but at last only three, Juno, Venus, and Minerva, wished to urge their respective claims to the prize, in virtue of superior beauty. The gods, unwilling to become arbiters in so delicate an affair, appointed Paris to adjudge the prize of beauty to the fairest of the goddesses; and indeed the shepherd seemed sufficiently qualified to decide so great a contest, as his wisdom was so well established, whilst his prudence and sagacity were also known. The goddesses appeared before their judge without any covering or ornament, and each endeavoured by promises and entreaties to gain the attention of Paris, and to influence his judgment. Juno promised him a kingdom, Minerva military glory, and Venus the fairest woman in the world for his wife. After he had heard their several claims and promises, Paris adjudged the prize to Venus, and gave her the golden apple, to which perhaps she seemed entitled as the goddess of beauty. This decision of Paris drew upon the judge and his family the resentment of the other two goddesses.

Soon afterwards Priam proposed a contest amongst his sons and other princes, and promised to reward the conqueror with one of the finest bulls of Mount Ida. His emissaries were sent to procure the animal, and it was found in the possession of Paris, who reluctantly yielded it. The shepherd, anxious to regain his favourite, went to Troy and entered the lists of the combatants. He was received with the greatest applause, and obtained the victory over his rivals, Nestor the son of Neleus, Cyenus the son of Neptune, Polites, Helenus, and Deiphobus, sons of Priam. He likewise obtained a superiority over Hector, who, enraged to see himself conquered by an unknown stranger, pursued him closely; and Paris must have fallen a victim to his brother's rage, had he not fled to the altar of Jupiter. This sacred retreat preserved his life; and Cassandra, the daughter of Priam, struck with the similarity of the features of Paris to those of her brothers, inquired his birth and age. From these circumstances, she soon discovered that he was her brother, and as such she introduced him to her father and to her brothers. Priam acknowledged Paris as his son, forgetful of the alarming dreams which had caused him to meditate his death: and all jealousy ceased amongst the brothers. Paris did not long suffer himself to remain inactive; he equipped a fleet, as if willing to redeem Hesione, his father's sister, whom Hercules had carried away and obliged to marry Telamon the son of Æacus. This was the pretended motive of his voyage, but the real causes were far different. Paris remembered that he was to be the husband of the fairest of women; and, if he had been led to form these expectations whilst he was an obscure shepherd of Ida, he had now every plausible reason to see them realized, since he was the acknowledged son of the king of Troy. Helen was the fairest woman of the age, and Venus had promised her to him. On these grounds, therefore, he went to Sparta, the residence of Helen, who had married Menelaus. He was received with great respect; but he abused the hospitality of Menelaus, and whilst the husband was absent in Crete, Paris persuaded Helen to elope with him, and to fly to Asia. Helen consented; and Priam received her into his palace without difficulty, as his sister was then detained in a foreign country, and as he wished to show himself as hostile as possible to the Greeks. This affair was soon productive of serious consequences. When Menelaus had married Helen, all her suitors had bound themselves by a solemn oath to protect her person, and therefore the injured husband reminded them of their engagements, and called upon them to recover her. Upon this all Greece took up arms in the cause of Menelaus; Agamemnon was chosen general of the combined forces, and a regular war commenced. Paris, meanwhile, who had refused Helen to the petitions and embassies of the Greeks, armed himself, with his brothers and subjects, to oppose the enemy; but the success of the war was neither hindered nor promoted by his means. He fought with little courage, and at the very sight of Menelaus, whom he had so recently injured, all his resolution vanished, and he retired from the front of the army, where he walked before like a conqueror. In a combat with Menelaus, which he undertook at the instigation of his brother Hector, Paris must have perished, had not Venus interfered, and stolen him from the resentment of his antagonist. In another battle, however, he wounded Machaon, Euryphilus, and Diomedes; and, according to some opinions, he killed with one of his arrows the great Achilles himself.

The death of Paris is differently related. Some say that he was mortally wounded by one of the arrows of Philoctetes, which had been once in the possession of Hercules; and that, when he found himself becoming languid on account of his wounds, he ordered himself to be carried to the feet of Œnone, whom he had basely abandoned, and who in the years of his obscurity had foretold him that he would solicit her assistance in his dying moments. But he expired before he came into the presence of Œnone; and the nymph, still mindful of their former loves, threw herself upon his body, and stabbed herself to the heart, after she had plentifully bathed it with her tears. According to others, Paris did not immediately proceed to Troy when he left the Peloponnesus, but was driven upon the coasts of Egypt, where Proteus, king of that country, detained him; and when he heard of the violence which had been offered to the king of Sparta, he kept Helen at his court, and permitted Paris to retire. Whatever was the mode of his death, it is said to have taken place about 1188 before Christ.

PARISH, the precinct of a parochial church, or a circuit of ground inhabited by people who belong to one church, and are under the particular charge of its minister. The word comes from the Latin *parochia*, and the Greek παροικια, *habitation*, compounded of παρα, *near*, and οικος, house. Accordingly, Du Cange observes, that the name παροικια was anciently applied to the whole territory of a bishop, because the primitive Christians, not daring to assemble openly in cities, were forced to meet secretly in the neighbouring houses.

In the ancient church there was one large edifice in each city for the people to meet in; and this they called *parochia*, or parish. But the signification of the word was afterwards enlarged, and by a parish was meant a diocese, or the extent of the jurisdiction of a bishop, consisting of several churches; unless we suppose, as some do, that those bishops were only pastors of single churches. Dupin observes, that country parishes were unknown before the fourth century; but those of cities are more ancient. The city of Alexandria is said to have been the first which was divided into parishes.

Of the first division of parishes there is no certain information; for in the early ages of Christianity in this island, parishes were unknown, or at least signified the same thing as diocese. There was then no appropriation of ecclesiastical dues to any particular church; but every man was at liberty to contribute his tithes to any priest or church that he pleased; or if he made no special appropriation of them, they were paid to the bishop, whose duty it was to distribute them amongst the clergy, and for other pious purposes, according to his own discretion. Camden says that England was divided into parishes by Archbishop Honorius, about the year 630. Sir Henry Hobart maintains that parishes were first erected by the council of Lateran, held in the year 1179. But Selden proves that the clergy lived in common, without any division of parishes, long after the time mentioned by Camden; and it appears from the Saxon laws, that parishes were in being long before the council of Lateran in 1179. The distinction of parishes first occurs in the laws of Edgar, about the year 970. It seems pretty certain, says Justice Blackstone (Com. vol. i. p. 112), that the boundaries of parishes were first ascertained by those of a manor or manors; because it very seldom happens that a manor extends itself over more than one parish, although there are often many manors in one parish. As Christianity spread, the lords began to build churches upon their own demesnes or wastes, in order to accommodate their tenants in one or two adjoining lordships; and, that they might have divine service regularly performed therein, they obliged all their tenants to appropriate their tithes to the maintenance of the one officiating minister, instead of leaving them at liberty to distribute them amongst the clergy of the diocese in general. The tract of land the tithes of which were thus appropriated formed a distinct parish; a circumstance which accounts for the frequent intermixture of parishes one with another. For if a lord had a parcel of land detached from the main part of his estate, but not sufficient to form a parish of itself, it was natural for him to endow his newly-erected church with the tithes of such lands.

Parish-Clerk. In every parish the parson, vicar, or curate has a parish-clerk under him, who is the lowest officer of the church. Parish-clerks were formerly clerks in orders, and their business at first was to officiate at the altar, for which they had a competent maintenance by offerings; but they are now laymen, and have certain fees at christenings, marriages, and burials, besides wages for their maintenance.

PARK (French *parque*, that is, *locus inclusus*) is a large extent of ground enclosed and privileged for wild beasts of chase, by the king's grant or prescription.

Manwood defines a chase a privileged place for beasts of venery, and other wild beasts of the forest and chase, *tam sylvestres quam campestres*. A park, therefore, differs from a chase or warren in this, that it must be enclosed; for if it lie open, this is a good cause of seizure by the king, as a thing forfeited.

Park, *Mungo*, a celebrated traveller, was born at Fowlshiels, near Selkirk, on the 10th of September 1771. His father occupied the farm of Fowlshiels, under the Duke of Buccleuch. He appears to have bestowed uncommon attention on the education of his children; and he even employed a tutor to reside in his house, an expense which was then supposed to exceed the resources of an ordinary farmer. Young Park made a good figure at school. His general demeanour was reserved and thoughtful; yet occasional sparks of ambition broke forth, indicative of that adventurous spirit which lay concealed under a somewhat cold exterior. This thoughtful disposition led his friends to consider the church as the profession best suited to his character; but as he himself preferred physic to theology, his wishes were acquiesced in; and he spent three years at the University of Edinburgh, in the studies necessary to qualify him for that profession.

At Edinburgh Park studied with ardour and success; and in particular he imbibed a fondness for botany, which served to give a strong colour to his future life. It strengthened his natural connection with his brother-in-law, Mr

James Dickson, who, notwithstanding many disadvantages, attained such skill in that science, that, on going as a gardener to Hammersmith, he obtained a large share of the patronage and favour of Sir Joseph Banks. This connection induced Mr Park to repair to London. He was introduced to Sir Joseph, who was so much pleased with him that he obtained for him the appointment of assistant-surgeon to the Worcester East Indiaman. In this capacity Mr Park performed a voyage to Bencoolen, where he made some collections and observations in botany and natural history, which were submitted to the Linnæan Society, and an account of them printed in the third volume of their Transactions.

The African Association were now anxiously looking out for a successor to Major Houghton, their unfortunate missionary, who had perished in the attempt to penetrate to the Niger and Timbuctoo. This opening, although foreign to any of Mr Park's former pursuits except that of natural history, was immediately embraced by him with an ardour which showed how congenial it was to the character of his mind. Without hesitation, he offered himself for this arduous and perilous service, and, being supported by the recommendation of Sir Joseph Banks, he was at once accepted.

Park spent about two years in and near London, acquiring the qualifications necessary for his mission. In May 1795 he set sail, and on the 21st of June following arrived at Jillifree, near the mouth of the Gambia. After spending some months with Dr Laidley at Pisania, in acquiring the Mandingo language, he, on the 2d of December 1795, departed on his grand expedition. It would be superfluous to enter here into a detail of events which are so generally known, and which excited so deep an interest, as his captivity amongst the Moors, his almost miraculous escape, his discovery of the course of the Niger, and of the African capital of Sego, his journey through Bambarra, and the train of peril and difficulty through which he effected his return. He arrived, after the length of his absence, and the want of intelligence respecting him, had nearly extinguished all hopes of his safety. Reaching London early in the morning of Christmas 1797, he went to pass the time before breakfast in the gardens of the British Museum, where, by a singular chance, he met Mr Dickson, who embraced his friend as one returned from the grave. An extraordinary interest in his adventures was immediately excited amongst the African Institution, its friends, and the public in general. Major Rennell drew up an important memoir, showing the new light thrown by his journey upon African geography, which, with an abstract of his narrative by Mr Bryan Edwards, was speedily offered, to satisfy the curiosity of the public. In the spring of 1799, Mr Park presented the public with a full narrative from his own pen. Major Rennell's memoir was appended, and a considerable part of Mr Edwards' abstract was incorporated verbatim; upon which circumstance alone seems to have been built the rumour of that gentleman having been the actual writer of the volume. The work was read with an avidity proportioned to the novelty and importance of the information contained in it, and to the interesting and agreeable manner in which the events were narrated.

Having finished this task, Mr Park seems to have resolved to retire into domestic and professional life. In 1799, he married Miss Anderson of Selkirk, daughter of the gentleman with whom he had served his apprenticeship as a surgeon. In October 1801, he embraced an opportunity which offered, of commencing a professional career at Peebles, and soon found himself in respectable practice. His situation now seemed sufficiently comfortable, being happy in domestic life, possessed of a competence, and surrounded by respectable society; but his active mind was not to be so satisfied, and was secretly panting after a higher sphere of exertion.

Important as were his discoveries, their effect had been, not to satisfy, but to excite still farther, the public curiosity. The course of the Niger through the unknown and central parts of the continent could not fail to excite peculiar interest. This was strongly felt, not only by the scientific world, but by some intelligent members of administration, who, on the conclusion of the peace in 1801, determined to fit out an expedition on a great scale, to effect the discovery of the termination of this great river. In autumn 1803, Lord Hobart, afterwards Earl of Buckinghamshire, who was then colonial secretary, offered the command of it to Mr Park, who, though he asked a short interval to consult his friends, seems never in his own mind to have hesitated as to its acceptance. To those who represented to him the dangers that were to be incurred, he urged, that the hardships attendant on the obscure exercise of his profession, his journeys to distant patients, his long and solitary rides over "cold and lonely heaths," and over "gloomy hills, assailed by the wintry tempest," would tend as effectually to shorten life as the journey now in contemplation.

In this new undertaking, Mr Park was amply supplied with every thing which could insure success. Thirty soldiers, and nearly the same number of carpenters and artificers, were placed under his command; arms, beasts of burden, and commodities to trade with, were amply supplied; and he was empowered to draw upon the treasury to the extent of L.5000. Everything, therefore, seemed to augur a still more brilliant issue to his present than to his former journey. But a dark destiny impended over it, and rendered abortive all human means and efforts.

It would be superfluous to enter into a detail of that afflicting train of events, with which the public are already but too well acquainted.[1] That Park perished in his voyage down the Niger, may be considered as long since fully established; and we need not swell our pages with the rumours which have been circulated respecting an event which has for many years ceased to be doubtful.

Park has been pronounced by some the first of modern travellers. Without altogether adopting this opinion, we may observe, that the problem of the course of the Niger, which he had the fortune partially to solve, was one which had involved in error almost all former geographical systems on Africa. D'Anville, indeed, had stated it correctly; but as he had not communicated the grounds upon which his conclusion rested, the opposite opinion, which represented the Niger as flowing westward, and joining the ocean by the channel of the Senegal, continued still prevalent. This point, finally decided, fixed the geographical character of the continent. In Bambarra, also, a name as yet scarcely heard of by Europeans, Park found a kingdom much farther advanced in populousness and civilization than had yet been supposed to exist in the heart of Africa.

Mr Park's literary, though not equal to his active qualifications, were nevertheless respectable. But notwithstanding his knowledge of botany, he cannot be considered as a scientific traveller. We see not in him that varied and splendid science which, in Humboldt, illustrates and adorns, though it sometimes overlays the main subject. But with arker.

---

[1] The Narrative of this journey was published in 1815, in 4to, with a very interesting biographical memoir and preface, by Mr Wishaw. It may not be amiss to notice here a singular oversight in Park's Journal, lately observed by M. Walckenaer. A 31st day is counted in April (p. 7); and as all the days before and after are accounted for, there can be no doubt that all the following dates are one day behind. This, as Mr Bowdich has shown, is not so trifling an error as at first sight it appears; for a false declination being thus taken, an error, greater or less, and sometimes not inconsiderable, is committed in the calculation of all the subsequent latitudes.

Parkur || Parliament.

regard to the general aspect of nature, and the forms of human society, his observations are careful, accurate, and judicious. Nothing can be more lively than the idea which we receive from him of the African forests and deserts, the cities of Bambarra, the stream of the Niger or Joliba, and the regions watered by that river. The spirit, joined to the unpretending simplicity, of his narrative, has rendered his work one of the most popular of its kind in the English language.

Mr Park's bodily frame was well fitted for the arduous enterprises in which he engaged. He was six feet in height, his limbs were well proportioned, and his whole frame was active and robust. His countenance was prepossessing, and his manners always retained their native plainness and simplicity. But this was combined with a natural coldness and reserve, which rendered his conversation less interesting than was expected by those who considered his general talents and extensive opportunities of observation. His conduct in all the relations of private life was highly exemplary. He left a widow, three sons, and a daughter. (E.)

PARKER, MATTHEW, the second Protestant archbishop of Canterbury, was born at Norwich in the year 1504, the 19th of Henry VII. His father, who was a man in trade, died when his son was about twelve years of age; but his mother took especial care of his education, and at the age of seventeen sent him to Corpus Christi College, Cambridge, where, in 1523, he took his bachelor's degree. In 1527 he was ordained, created master of arts, and chosen fellow of the college. Having obtained a license to preach, he frequently discoursed at St Paul's cross in London, and in other parts of the kingdom. In the year 1533 or 1534, he was made chaplain to Anne Boleyn, who obtained for him the deanery of Stoke Clare in Suffolk, where he founded a grammar-school. After the death of this unfortunate woman, Henry made him his own chaplain, and in 1541 appointed him prebendary of Ely. In 1544, he was, by the king's command, elected master of Corpus Christi College, and the following year appointed vice chancellor of the university. In 1547 he lost the deanery of Stoke, by the dissolution of that college. In the same year he married the daughter of Mr Robert Harlestone, a Norfolk gentleman.

In the year 1552 he was nominated by Edward VI. to the deanery of Lincoln, which, with his other preferments, enabled him to live in great affluence. But Mary had scarcely succeeded to the throne when he was deprived of every office he held in the church, and obliged to live in obscurity, frequently changing his place of abode to avoid the fate of the other reformers.

Elizabeth ascended the throne in 1558; and in the following year Parker was at once raised from indigence and obscurity to the see of Canterbury, an honour which he had neither solicited nor desired. In this high station he acted with equal spirit and propriety. He founded several scholarships in Bennet or Corpus Christi College, Cambridge, and made large presents of plate to that and to other colleges in this university. He gave a hundred volumes to the public library; and, besides, founded a free school at Rochdale in Lancashire. He took care to have the different sees filled with pious and learned men; and, considering the great want of Bibles in many places, he, with the assistance of other learned men, improved the English translation, which he caused to be printed on large paper, and dispersed throughout the kingdom. This estimable prelate died in the year 1575, aged seventy-two, and was buried in his own chapel at Lambeth. He was pious without affectation or austerity, cheerful and contented in the midst of adversity, moderate in the height of power, and beneficent beyond example. He was the author of several works, and likewise published four of our best historians; Matthew of Westminster, Matthew Paris, Asser's Life of King Alfred, and Thomas Walsingham. The archbishop also translated the Psalter. This version was printed, but without a name, and has been attributed to an obscure poet of the name of Keeper. Such, at least, was Wood's opinion, although it is more than probable that he was wrong. But in the Gentleman's Magazine for 1781 (p. 566), Parker is proved to be the author of a version of the Psalms.

PARKUR, a small district of Hindustan, situated about the twenty-fourth degree of north latitude. This part of the country has been seldom visited by Europeans, but is described by the natives as of a sandy and rocky nature, ill supplied with water. It has to the north the sandy desert, to the south Cutch, to the east Gujerat, and to the west the province of Sinde. There is no cultivation, except by means of irrigation from wells or tanks. The territory is said to contain between forty and fifty villages.

PARLEY, a conference with an enemy. To beat or to sound a parley is therefore to give a signal for holding such a conference, by beat of drum or sound of trumpet.

PARLIAMENT, the grand assembly of the three estates of the kingdom, summoned together by the king's authority, to consider of matters relating to the public welfare, and particularly to enact and repeal laws.

The original institution of parliament is one of those matters which lie so far hidden in the obscurity of antiquity, that the tracing of it out is a task difficult in itself, and not likely to be productive of any satisfactory result. The term *parliament* itself is comparatively of modern date, being derived from a French word, and signifying the place where they met and conferred together. It was first applied to general assemblies of the states under Louis VII. in France, about the middle of the twelfth century. But it is certain that, long before the introduction of the Norman language into England, all matters of importance were debated and settled in the great council of the realm; a practice which seems to have been universal amongst the northern nations, particularly the Germans, and which was carried by them into all the countries of Europe which they overran at the dissolution of the Roman empire. Relics of this constitution, under various modifications and changes, are still to be met with in the diets of Poland, Germany, and Sweden.

In England, however, this general council has been held immemorially, under the several names of *michel-synoth*, or great council; *michel-gemote*, or great meeting; and more frequently *wittena-gemote*, or the meeting of wise men. It was also styled in Latin, *commune concilium regni, magnum concilium regis, curia magna, conventus magnatum vel procerum, assisa generalis*, and sometimes *communitas regni Angliæ*. We have instances of its meeting to order the affairs of the kingdom, to make new laws and to amend the old, or, as Fleta expresses it, *novis injuriis emersis nova constituere remedia*, as early as the reign of Ina king of the West Saxons, Offa king of the Mercians, and Ethelbert king of Kent, in the several realms of the heptarchy. But, after their union, the Mirrour informs us that Alfred ordained as a perpetual usage, that these councils should meet twice in the year, or oftener if need be, to treat of the government of God's people, and how they should keep themselves from sin, live in quiet, and receive right. The succeeding Saxon and Danish monarchs held frequent councils of this sort, as appears from their respective codes of laws, the titles of which usually indicate that they were enacted, either by the king with the advice of his *wittena-gemote* or wise men, as, *Hæc sunt instituta, quæ Edgarus rex consilio sapientium suorum instituit*; or by those sages with the advice of the king, as, *Hæc sunt judicia quæ sapientes consilio regis Ethelstan instituerunt*; or, lastly, by both together, as, *Hæ sunt institutiones, quas rex Edmundus et episcopi sui cum sapientibus suis instituerunt.*

There is also no doubt that these great councils were occasionally held under the first princes of the Norman line. Glanvil, who wrote in the reign of Henry II. speaking of the particular amount of an amercement in the sheriff's court, says it had never yet been ascertained by the general assize or assembly, but was left to the custom of particular counties. Here the general assize is spoken of as a meeting well known, and its statutes or decisions are referred to in manifest contradistinction to custom or to the common law. And in the time of Edward III. an act of parliament, made in the reign of William the Conqueror, was pleaded in the case of the Abbey of St Edmund's Bury, and judicially allowed by the court.

Hence it indisputably appears that parliaments or general councils were coeval with the kingdom itself. How those parliaments were constituted and composed is another question, which has been matter of great dispute amongst our learned antiquaries; and, particularly, whether the Commons were summoned at all, or, if summoned, at what period they began to form a distinct assembly. But without entering into controversies of this kind, it may be sufficient to observe here, that it is generally agreed, that, in the main, the constitution of parliament, as it now exists, was marked out as long ago as the seventeenth year of King John, 1215, in the Great Charter granted by that monarch, in which he promises to summon all archbishops, bishops, abbots, earls, and greater barons, personally, and all other tenants in chief under the crown, by the sheriff and bailiffs, to meet at a certain place, upon forty days' notice, to assess aids and scutages when necessary. And this constitution subsisted at least from the year 1266, or the 49th of Henry III., there being still extant writs of that date, to summon knights, citizens, and burgesses, to attend parliament. We proceed therefore to inquire wherein consists this constitution of parliament as it now stands; and, in the prosecution of this inquiry, we shall consider, first, the manner and time of its assembling; secondly, its constituent parts; thirdly, the laws and customs relating to parliament; fourthly, the methods of proceeding, and of enacting statutes, in both houses; and, lastly, the manner of the parliament's adjournment, prorogation, and dissolution.

1. The parliament is to be regularly summoned by the king's writ or letter, issued out of chancery, by advice of the privy council, at least forty days before it begins to sit. It is a branch of the royal prerogative that no parliament can be convened by its own authority, or by the authority of any excepting the king alone; and this prerogative is founded upon very good reason. For, supposing it had a right to meet spontaneously, without being called together, it is impossible to conceive that all the members, and each of the houses, would agree unanimously upon the proper time and place of meeting; and if half of the members met, and half absented themselves, who could determine which was really the legislative body, the part assembled, or that which staid away? It is therefore necessary that the parliament should be called together at a determinate time and place, and it is highly becoming its dignity and independence that it should be called together by none but one of its own constituent parts; but, of the three constituent parts, this office can only appertain to the king, as he is a single person, whose will may be uniform and steady, the first person in the nation, being superior to both houses in dignity, and the only branch of the legislature which has a separate existence, and is capable of performing any act at a time when no parliament is in being. Nor is it an exception to this rule, that, by some modern statutes, on the demise of a king or a queen, if there be then no parliament in being, the last parliament revives, and is to sit again for six months, unless dissolved by the successor; for this revived parliament must have been originally summoned by the crown.

It is true indeed that the Convention Parliament, which restored Charles II., met above a month before his return, the Lords by their own authority, and the Commons in pursuance of writs issued in the name of the keepers of the liberty of England by authority of parliament; and that the said parliament sat till the 29th of December, fully seven months after the Restoration, and enacted many laws, several of which still remain in force. But this was from the necessity of the case, which supersedes all law; for if they had not so met, it would have been morally impossible that the kingdom could have been settled in peace. The first thing, however, which was done after the king's return, was, to pass an act declaring this to be a good parliament, notwithstanding the defect of the king's writ; so that as the royal prerogative was chiefly wounded by their so meeting, and as the king himself, who alone had a right to object, consented to waive the objection, this cannot be drawn into an example in prejudice of the rights of the crown. Besides, we should also remember, that there existed at that time great doubt amongst the lawyers, whether even this healing act made it a good parliament; and indeed it was held by many in the negative, though this seems to have been too nice a scruple. But, out of abundant caution, it was thought necessary to confirm its acts in the next parliament, by statute 13 Car. II. c. 7 and c. 14.

It is likewise true, that at the time of the Revolution in 1688, the Lords and Commons, by their own authority, and upon the summons of the Prince of Orange, afterwards William III., met in a convention, and therein disposed of the crown and kingdom. But it must be remembered, that this assembling was held upon a similar principle of necessity as at the Restoration, that is, upon a full conviction that James II. had abdicated the government, and that the throne was thereby vacant; and this supposition of the individual members was confirmed by their concurrent resolution when they actually came together. In such a case as the palpable vacancy of a throne, it follows, *ex necessitate rei*, that the form of the royal writs must be laid aside, otherwise no parliament could ever meet again. For let us put another possible case, and suppose, for the sake of argument, that the whole royal line should at any time fail and become extinct, which would indisputably vacate the throne; in this situation it seems reasonable to presume that the body of the nation, consisting of Lords and Commons, would have a right to meet and to settle the government. But upon this and no other principle did the Convention assemble in 1688. The vacancy of the throne preceded their meeting without any royal summons, and was not a consequence of it. They did not assemble without writ, and then declare the throne vacant; but, the throne being previously vacant by the king's abdication, they assembled without writ, as they must have done if they assembled at all. Had the throne been full, their meeting would not have been regular; but, as it was really empty, such meeting became absolutely necessary. Accordingly, it is declared by statute (1 William and Mary, stat. i. c. 1), that this Convention was really the two houses of parliament, notwithstanding the want of writs, or other defects of form; so that, notwithstanding these two capital exceptions, which were justifiable only on a principle of necessity, and each of which, by the way, induced a revolution in the government, the rule laid down is in general certain, that the king only can convoke a parliament.

And this, by the ancient statutes of the realm, he is bound to do every year, or oftener if need be. Not that he is, or ever was, obliged by these statutes to call a new parliament every year; but only to permit a parliament to sit annually for the redress of grievances, and the despatch of business, if need be. These last words are so loose and vague, that such of our monarchs as were inclined to govern without parliaments neglected the convoking of them, sometimes for a very considerable period, under pretence that there was not need of them. But, to remedy this, by the statute 16 Car. II. c. 1, it is enacted, that the sitting and holding of parliaments shall not be intermitted above three years at the most; and by the 1st of William and Mary, stat. ii, c. 2, it is declared to be one of the rights of the people, that, for the redress of all grievances, and for the amending, strengthening, and preserving of the laws, parliaments ought to be held frequently. And this indefinite frequency is again reduced to a certainty by statute 6 William and Mary, c. 2, which enacts, as the statute of Charles II. had before done, that a new parliament shall be called within three years after the determination of the former.

2. The constituent parts of a parliament are, the king's majesty, sitting there in his royal political capacity; and the three estates of the realm—the Lords Spiritual, and the Lords Temporal, who sit together with the king in one house, and the Commons, who sit by themselves in another. The king and these three estates taken together form the great corporation or body politic of the kingdom, of which the king is said to be *caput, principium, et finis.* For upon their assembling, the king meets them, either in person or by representation, without which there can be no beginning of a parliament; and he alone possesses the power of dissolving them.

It is highly necessary, for preserving the balance of the constitution, that the executive power should be a branch, though not the whole, of the legislature. The total union of them, we have seen, would be productive of tyranny; the total disjunction of them, for the present, would in the end produce the same effects, by causing that union against which it seems to provide. The legislature would soon become tyrannical, by making continual encroachments, and gradually assuming to itself the rights of the executive power. Thus the long parliament of Charles I., whilst it acted in a constitutional manner, with the royal concurrence, redressed many heavy grievances, and established many salutary laws. But when the two houses assumed the power of legislation, exclusively of the royal authority, they soon afterwards assumed the reins of administration; and, in consequence of these united powers, overturned both church and state, and established a worse oppression than any they pretended to remedy. To prevent any such encroachments, the king is himself a part of the parliament; and as this is the reason of his being so, the share of legislation which the constitution has placed in the crown consists in the power of rejecting rather than resolving, this being sufficient to answer the end proposed. For we may apply to the royal negative, in this instance, what Cicero observes of the negative of the Roman tribunes, that the crown has not any power of doing wrong, but merely of preventing wrong being done. The crown cannot begin of itself any alterations in the established law; but it may approve or disapprove of the alterations suggested and consented to by the two houses. The legislature, therefore, cannot abridge the executive power of any rights which it now has by law, without its own consent, since the law must perpetually stand as it now does, unless all the powers agree to alter it; and herein consists the true excellence of the British government, that all its parts form a mutual check upon each other. In the legislature, the people are a check upon the nobility, and the nobility a check upon the people, by the mutual privilege of rejecting each what the other has resolved; whilst the king is a check upon both, which preserves the executive power from encroachments. But this very executive power is again checked and kept within due bounds by the two houses, through the privilege they possess of inquiring into, impeaching, and punishing the conduct of evil and pernicious counsellors. Thus every branch of our civil polity supports and is supported, regulates and is regulated, by the rest. For the two houses naturally drawing in two directions of opposite interest, and the prerogative in another different from them both, they mutually keep each other from exceeding their proper limits; whilst the whole is prevented from separation, and artificially connected together, by the mixed nature of the crown, which is part of the legislature, and the sole executive magistrate. Like three distinct powers in mechanics, they jointly impel the machine of government in a direction different from what either, acting by itself, would have done; but at the same time in a direction partaking of each separate impulsion, and formed out of all, constituting the true line of the liberty and happiness of the community.

3. The power and jurisdiction of parliaments, says Sir Edward Coke, is so transcendent and absolute, that it cannot be confined either for causes or persons within any bounds; and of this high court, he adds, it may be truly said, *Si antiquitatem spectes, est vetustissima; si dignitatem, est honoratissima; si jurisdictionem, est capacissima.* It has sovereign and uncontrollable authority in making, confirming, enlarging, restraining, abrogating, repealing, reviving, and expounding laws, concerning matters of all possible denominations, ecclesiastical or temporal, civil, military, maritime, or criminal; this being the depository where that absolute power, which must in all governments reside somewhere, is intrusted by the constitution of these kingdoms. All mischiefs and grievances, operations and remedies, which transcend the ordinary course of the laws, are within the reach of this extraordinary tribunal. It can regulate or new-model the succession to the crown, as was done in the reigns of Henry VIII. and William III. It can alter the established religion of the land, as was done in a variety of instances in the reigns of Henry VIII. and his three children. It can change and create afresh even the constitution of the kingdom and of parliaments, as was done by the act of Union, and the several statutes for triennial and septennial elections. It can, in short, do every thing that is not naturally impossible; and therefore some have not scrupled to call its power, by a figure rather too bold, the "omnipotence of parliament." True it is, however, that what the parliament does, no authority upon earth can undo; so that it is a matter most essential to the liberties of this kingdom, that such members be delegated to this important trust as are most eminent for their probity, their fortitude, and their knowledge. For it was a known apophthegm of Lord Treasurer Burghley, that England could never be ruined but by a parliament; and, as Sir Matthew Hale observes, this being the highest and greatest court, over which none other can have jurisdiction in the kingdom, if by any means a misgovernment should anyway fall upon it, the subjects of this kingdom are left without any manner of remedy. To the same purpose Montesquieu, though we trust too hastily, presages, that as Rome, Sparta, and Carthage, have lost their liberty and perished, so the constitution of England will in time lose its liberty and perish; it will perish, says he, whenever the legislative power shall become more corrupt than the executive.

To prevent the mischiefs which might arise by placing this extensive authority in hands that are either incapable or unfit to manage it, it is provided by the custom and law of parliament, that no one shall sit or vote in either house, unless he be twenty-one years of age. This is also expressly declared by statute 7 and 8 William III. c. 25. With regard to the House of Commons, doubts have arisen, from some contradictory judgments, whether or not a minor was incapacitated from sitting in that house. It is also enacted by statute 7 Jac. I. c. 6, that no member shall be permitted to enter the House of Commons till he has taken the oath of allegiance before the Lord Steward or his deputy; and by 30 Car. II. st. ii., and 1 Geo. I. c. 13, it is provided that no member shall sit or vote in either house, till he has, in the presence of the house, taken the oaths of allegiance, supremacy, and abjuration, and subscribed and repeated the declaration against transubstantiation, the invocation of saints, and the sacrifice of the mass. Aliens, unless naturalized, were likewise by the law of parliament incapable of serving therein; and it is enacted by statute 12 and 13 William III. c. 2, that no alien, even though he be naturalized, shall be capable of being a member of either house of parliament. But these are not the only standing incapacities. If any person be made a peer by the king, or elected to serve in the House of Commons by the people, yet may the respective houses, upon complaint of any crime committed by such person, and proof thereof, adjudge him disabled and incapable to sit as a member; and this by the law and custom of parliament.

For as every court of justice has laws and customs for its direction, some the civil and canon, some the common law, others their own peculiar laws and customs, so the high court of parliament has also its own peculiar law, called the *lex et consuetudo parliamenti;* a law which, Sir Edward Coke observes, is *ab omnibus quærenda, a multis ignorata, a paucis cognita.* It will not therefore be expected that we should enter into the examination of this law with any degree of minuteness; since, as the same learned author assures us, it is much better to be learned from the rolls of parliament and other records, and by precedents and continual experience, than can be expressed by any one man. It will be sufficient to observe, that the whole of the law and custom of parliament has originated from this one maxim, "that whatever matter arises concerning either house of parliament, ought to be examined, discussed, and adjudged in that house to which it relates, and not elsewhere." Hence, for instance, the Lords will not suffer the Commons to interfere in settling the election of a peer in Scotland; the Commons will not allow the Lords to judge of the election of a burgess; nor will either house permit the subordinate courts of law to examine the merits of either case. But the maxims upon which they proceed, together with the method of proceeding, rest entirely in the breast of the parliament itself, and are not defined or ascertained by any particular or stated laws.

The privileges of parliament are likewise very large and indefinite; and therefore, when in the 31st of Henry VI. the House of Lords propounded a question to the judges concerning them, the chief justice, Sir John Fortescue, in the name of his brethren, declared, "That they ought not to make answer to that question; for it hath not been used aforetime that the justices should in anywise determine the privileges of the high court of parliament; for it is so high and mighty in its nature that it may make law, and that which is law it may make no law; and the determination and knowledge of that privilege belong to the lords of parliament, and not to the justices." Privileges of parliament were principally established in order to protect its members, not only from being molested by their fellow-subjects, but more especially from being oppressed by the power of the crown. If therefore all the privileges of parliament were once to be set down and ascertained, and no privilege to be allowed but what was so defined and determined, it were easy for the executive power to devise some new case not within the line of privilege, and under pretence thereof to harass any refractory member, and to violate the freedom of parliament. The dignity and independence of the two houses are therefore in a great measure preserved by keeping their privileges indefinite. Some, however, of the more notorious privileges of the members of either house are, privilege of speech, of person, of their domestics, and of their lands and goods. As to the first, the privilege of speech, it is declared by the statute 1 William and Mary, st. ii. c. 2, as one of the liberties of the people, "that the freedom of speech, and debates, and proceedings in parliament, ought not to be impeached or questioned in any court or place out of parliament;" and this freedom of speech is particularly demanded of the king in person by the speaker of the House of Commons at the opening of every new parliament. So likewise are the other privileges of person, servants, lands, and goods, which are immunities as ancient as Edward the Confessor, in whose laws we find this precept: *Ad synodos venientibus, sive summoniti sint, sive per se quid agendum habuerint, sit summa pax;* and so too in the old Gothic constitutions, *Extenditur hæc pax et securitas ad quatuordecim dies, convocato regni senatu.* This formerly included not only privilege from illegal violence, but also from legal arrests and seizures by process from the courts of law; and still to assault by violence a member of either house, or his menial servants, is a high contempt of parliament, and there punished with the utmost severity. It has likewise peculiar penalties annexed to it in the courts of law by the statutes 5 Henry IV. c. 6, and 11 Henry VI. c. 11. Nor can any member of either house be arrested and taken into custody without a breach of the privilege of parliament.

But all other privileges which derogate from the common law are now at an end, save only as to the freedom of the member's person; which in a peer, by the privilege of peerage, is for ever sacred and inviolable, and in a commoner, by the privilege of parliament, for forty days after every prorogation, and forty days before the next appointed meeting, which is now in effect as long as the parliament subsists, since it is seldom prorogued for more than eighty days at a time. As to all other privileges which obstruct the ordinary course of justice, they were restrained by the statutes 12 William III. c. 3, 2 and 3 Anne, c. 18, and 11 Geo. II. c. 24, and are now totally abolished by statute 10 Geo. III. c. 50, which enacts, that any suit may at any time be brought against any peer or member of parliament, their servants, or any other person entitled to privilege of parliament; and that it shall not be impeached or delayed by pretence of any such privilege, except that the person of a member of the House of Commons shall not thereby be subjected to any arrest or imprisonment. Likewise, for the benefit of commerce, it is provided by statute 4 Geo. III. c. 33, that any trader, having privilege of parliament, may be served with legal process for any just debt to the amount of L.100; and, unless he make satisfaction within two months, it shall be deemed an act of bankruptcy; and commissions of bankruptcy may be issued against such privileged traders, in like manner as against any other.

The only way by which courts of justice could anciently take cognizance of privilege of parliament was by writ of privilege, in the nature of a *supersedeas,* to deliver the party out of custody when arrested in a civil suit. For when a letter was written by the speaker to the judges to stay proceedings against a privileged person, they rejected it, as contrary to their oath of office. But since the statute 12 William III. c. 3, which enacts, that no privileged person shall be subject to arrest or imprisonment, it has been held that such arrest is irregular *ab initio,* and that the party may be discharged upon motion. It is to be observed, that there is no precedent of any such writ of privilege, but only in civil suits; and that the statute of 1 Jac. I. c. 13, and that of William III., which remedy some inconveniences arising from privilege of parliament, speak only of civil actions. Therefore the claim of privilege has usually been guarded with an exception as to the case of indictable crimes; or, as it has been frequently expressed, of treason, felony, and breach of the peace. Hence it seems to have been understood that no privilege was allowable to the members, their families, or servants, in any crime whatsoever; for all crimes are treated by the law as being *contra pacem domini regis*. Instances have not been wanting in which privileged persons have been convicted of misdemeanors, and committed, or prosecuted to outlawry, even in the middle of a session; proceedings which have afterwards received the sanction and approbation of parliament. To this it may he added, that the case of writing and publishing seditious libels was resolved by both houses not to be entitled to privilege; and the reasons upon which that case proceeded extended equally to every indictable offence. Thus the chief, if not the only privilege of parliament, in such cases, seems to be the right of receiving immediate information of the imprisonment or detention of any member, with the reason for which he is detained; a practice that is daily used upon the slightest military accusations, preparatory to a trial by a court martial, and which is recognised by the several temporary statutes for suspending the *habeas corpus* act, by which it is provided, that no member of either house shall be detained, till the matter of which he stands suspected be first communicated to the house of which he is a member, and the consent of the said house obtained for his commitment or detaining. But ever since the Revolution the usage has uniformly been to make the communication subsequently to the arrest.

4. For the despatch of business, each house of parliament has its speaker. The speaker of the House of Lords, whose office it is to preside there, and manage the formality of business, is the Lord Chancellor, or keeper of the king's great seal, or any other appointed by the king's commission; and if none be so appointed, the House of Lords may elect their own speaker. The speaker of the House of Commons is chosen by the house, but must be approved by the king. And herein the usage of the two houses differs. The speaker of the House of Commons cannot give his opinion or argue any question in the house; but the speaker of the House of Lords, if a lord of parliament, may do so. In each house the act of the majority binds the whole; and this majority is declared by votes openly and publicly given, not, as in Venice, and many other senatorial assemblies, privately or by ballot. The latter method may be serviceable, to prevent intrigues and unconstitutional combinations; but it is impossible to be practised with us, at least in the House of Commons, where every member's conduct is subject to the future censure of his constituents, and therefore should be openly submitted to their inspection.

5. It now only remains to add a word or two concerning the manner in which parliament may be adjourned, prorogued, or dissolved.

An adjournment is no more than a continuance of the session from one day to another, as the word itself signifies; and this is done by the authority of each house separately every day, and sometimes for a fortnight or a month together, as at Christmas or Easter, or upon other particular occasions. But the adjournment of one house is no adjournment of the other. It has also been usual, when his majesty has signified his pleasure, that both or either of the houses should adjourn themselves to a certain day, to obey the king's pleasure so signified, and to adjourn accordingly. Otherwise, besides the indecorum of a refusal, a prorogation would assuredly follow, and would often be very inconvenient both to public and to private business. For prorogation puts an end to the session; and then such bills as are only begun and not perfected must be resumed *de novo*, if at all, in a subsequent session; whereas, after an adjournment, all things continue in the same state as at the time of the adjournment, and may be proceeded in without any fresh commencement.

A prorogation is the continuance of the parliament from one session to another, as an adjournment is a continuation of the session from day to day. This is done by the royal authority, expressed either by the Lord Chancellor in his majesty's presence, or by commission from the crown, or frequently by proclamation. Both houses are necessarily prorogued at the same time, it not being a prorogation of the House of Lords or Commons, but of the parliament. The session is never understood to be at an end until a prorogation takes place; although, unless some act be passed, or some judgment given in parliament, it is in truth no session at all. Formerly the usage was, for the king to give the royal assent to all such bills as he approved, at the end of every session, and then to prorogue the parliament, though sometimes only for a day or two, after which all business then depending in the houses was to be begun again. This custom obtained so strongly, that it once became a question, whether giving the royal assent to a single bill did not of course put an end to the session. But though it was then resolved in the negative, yet the notion was so deeply rooted, that the statute 1 Car. I. c. 7, was passed to declare that the king's assent to that and some other acts should not put an end to the session; and even as late as the reign of Charles II. we find a proviso frequently tacked to a bill, that his majesty's assent thereto should not determine the session of parliament. But it seems to be allowed, that a prorogation must be expressly made, in order to determine the session; and if, at the time of an actual rebellion, or imminent danger of invasion, the parliament shall be separated by adjournment or prorogation, the king is empowered to call them together by proclamation, on fourteen days' notice of the time appointed for their re-assembling.

A dissolution is the civil death of the parliament; and this may be effected in three ways.

The first is, by the king's will, expressed either in person or by representation. For as the king has the sole right of convening the parliament, so also it is a branch of the royal prerogative, that he may, whenever he pleases, prorogue the parliament for a time, or put a final period to its existence. If no one had a right to prorogue or dissolve a parliament but itself, it might happen to become perpetual; and this would be extremely dangerous, if at any time it should attempt to encroach upon the executive power, as was fatally experienced by the unfortunate Charles I., who, having unadvisedly passed an act to continue the parliament then in being till such time as it should please to dissolve itself, at last fell a sacrifice to that inordinate power which he had himself consented to give them. It is therefore extremely necessary that the crown should be empowered to regulate the duration of these assemblies, under the limitations which the English constitution has prescribed; so that, on the one hand, they may frequently and regularly meet together for the despatch of business and redress of grievances, and, on the other, may not, even with the consent of the crown, be continued to an inconvenient or unconstitutional length.

Secondly, a parliament may be dissolved by the demise of the crown. This dissolution formerly happened immediately upon the death of the reigning sovereign; for he being considered in law as the head of the parliament (*caput, principium, et finis*), when that failed, the whole body was held to be extinct. But the calling a new parliament immediately on the inauguration of the successor being found inconvenient, and dangers being apprehended from having no parliament in being in case of a disputed succession, it was enacted by the statutes 7 and 8 William III. c. 15, and 6 Anne, c. 7, that the parliament in being should continue for six months after the death of any king or queen, unless sooner prorogued or dissolved by the successor; that if the parliament, at the time of the king's death, had been separated, by adjournment or prorogation, it should notwithstanding assemble immediately; and that if no parliament was then in being, the members of the last parliament should assemble and be again a parliament.

Lastly, a parliament may be dissolved or expire by mere length of time. If the legislative body were perpetual, or if it lasted during the life of the prince who convened it, as formerly, and were to be supplied, by occasionally filling up the vacancies with new representatives; in these cases, were it once corrupted, the evil would be past all remedy: but when different bodies succeed each other, if the people see cause to disapprove of the present, they may rectify its faults in the next. A legislative assembly, also, which is sure to be separated, and its members to become private men, subject to the full operation of the laws which they have enacted for others, will think themselves bound in interest as well as in duty to make only such laws as are good. The utmost extent of time that the same parliament was allowed to sit, by the statute 6 William and Mary c. 3, was three years; after the expiration of which, reckoning from the return of the first summons, the parliament was to have no longer continuance. But by the 1st of Geo. I. stat. ii. c. 38, professedly enacted to prevent the great and continued expenses of frequent elections, and the violent heats and animosities consequent thereupon, and for the peace and security of the government, then just recovering from the effects of a rebellion, this term was prolonged to seven years; and, what alone is an instance of the vast authority of parliament, the very same house which was chosen for three years, enacted its own continuance for seven. As the constitution now stands, therefore, the parliament must expire, or die a natural death, at the end of every seventh year, if not sooner dissolved by the royal prerogative.

We shall conclude this article with an account of some general forms not noticed under any of the preceding heads.

In the House of Lords, the princes of the blood sit by themselves on the sides of the throne; and at the wall, upon the king's right hand, the two archbishops sit by themselves on a form. Below them, the bishops of London, Durham, and Winchester, and all the other bishops sit according to the priority of their consecration. On the king's left hand the Lord Treasurer, Lord President, and Lord Privy Seal, sit upon forms above all dukes, except those of the royal blood; then the dukes, marquises, and earls according to their creation. Across the room are wool sacks, continued from an ancient custom; and the Chancellor or Keeper, being of course the speaker of the House of Lords, sits on the first wool sack before the throne, with the great seal or mace lying by him; and below these there are forms for the viscounts and barons. On the other wool sacks are seated the judges, masters in chancery, and king's counsel, who are only to give their advice in points of law; but they all stand up till the king gives them leave to sit.

The Commons sit promiscuously, only the speaker has a chair at the upper end of the house, and the clerk and his assistant sit at a table near him. When a member of the House of Commons speaks, he stands up uncovered, and directs his address to the speaker only. If what he says be answered by another, he is not allowed to reply the same day, unless personal reflections have been cast upon him; but when the Commons, in order to have greater freedom of debate, have resolved themselves into a committee of the whole house, every member may speak to a question as often as he thinks necessary. In the House of Lords they vote, beginning at the puisne or lowest baron, and so up orderly to the highest, every one answering *content* or *not content*. In the House of Commons they vote by *yeas* and *nays*; and if it be dubious which are the greater number, the house divides. If the question be about bringing any thing into the house, the *yeas* go out, but if it be about any thing the house already has, the *nays* go out. In all divisions the speaker appoints four tellers, two of each opinion. In a committee of the whole house, they divide by changing sides, the *yeas* taking the right and the *nays* the left of the chair; and then there are but two tellers. If a bill pass one house, and the other demur to it, a conference is demanded in the painted chamber, where certain members are deputed from each house; and here the Lords sit covered, whilst the Commons stand bare, and debate the case. If they disagree, the affair is null; but if they agree, this, with the other bills which have passed both houses, is brought down to the king in the House of Lords, who comes thither clothed in his royal robes. Before him the clerk of the parliament reads the title of each bill, and as he reads, the clerk of the crown pronounces the royal assent or dissent. If it be a public bill, the royal assent is given in these words, *Le roy le veut,* The king will have it so; if a private bill, *Soit fait comme il est desiré,* Let the request be complied with: but if the king refuse the bill, the answer is, *Le roy s'avisera,* The king will think of it; and if it be a money bill, the answer is, *Le roy remercie ses loyaux sujets, accepte leur benevolence, et aussi le veut,* The king thanks his loyal subjects, accepts their benevolence, and therefore grants his consent.

High Court of PARLIAMENT is the supreme court in the kingdom, not only for the making, but also for the execution of laws, by the trial of great and enormous offenders, whether Lords or Commoners, in the method of parliamentary impeachment. As for acts of parliament to attaint particular persons of treason or felony, or to inflict pains and penalties, beyond or contrary to the common law, in order to serve a special purpose, we speak not of them; they are to all intents and purposes new laws, made *pro re nata,* and by no means an execution of such as are already in being. But an impeachment before the Lords by the Commons of Great Britain in parliament, is a prosecution of the already known and established law, and has been frequently put in practice; being a presentment to the highest or supreme court of criminal jurisdiction by the most solemn grand inquest of the whole kingdom. A commoner cannot, however, be impeached before the Lords for any capital offence, but only for high misdemeanors; but a peer may be impeached for any crime. In the case of an impeachment of a peer for treason, the Lords usually address the crown to appoint a lord high steward, for the greater dignity and regularity of their proceedings; and this high steward was formerly elected by the peers themselves, though he was generally commissioned by the king; but it has latterly been strenuously maintained, that the appointment of a high steward in such cases is not indispensably necessary, and that the house may proceed without one. The articles of impeachment are a kind of bills of indictment, found by the House of Commons, and afterwards tried by the Lords, who in cases of misdemeanors are considered not only as their own peers, but likewise as the peers of the whole nation. This is a custom derived from the constitution of the ancient Germans, who, in their great councils, sometimes tried capital accusations relating to the public: *Licet apud concilium accusare quoque, et discrimen capitis intendere.* And it has a peculiar propriety in the English constitution, which has much improved upon the ancient model imported hither from the Continent. For although the union of the legislative and judicial powers ought in general to be most carefully avoided, yet it may happen that a subject, intrusted with the administration of public affairs, may infringe the rights of the people, and be guilty of such crimes as the ordinary magistrate either dares not or cannot punish. Of these the representatives of the people, or the House of Commons, cannot properly judge, because their constituents are the parties injured, and can therefore only impeach. But before what court shall this impeachment be tried? Not before the ordinary tribunals, which would naturally be swayed by the authority of so powerful an accuser. Reason therefore suggests that this branch of the legislature, which represents the people, must bring its charge before the other branch, which consists of the nobility, who have neither the same interests, nor the same passions, as popular assemblies. The constitution of our island enjoys this vast superiority over those of the Grecian and Roman republics, where the people were at the same time judges and accusers, and where the accused were continually liable to become the victims of popular prejudice, passion, and resentment. It is therefore proper that the nobility should judge, to insure justice to the accused, as it is proper that the people should accuse, to insure justice to the commonwealth. Amongst other extraordinary circumstances attending the authority of this court, there is one of a very singular nature, which was insisted on by the House of Commons in the case of the Earl of Danby in the reign of Charles I., and is now enacted by statute 12 and 13 William III. c. 2, that no pardon under the great seal shall be pleadable to an impeachment by the Commons of Great Britain in parliament.

For a more general view of the British Constitution, the reader is referred to the article ENGLAND.

PARMA, a sovereign state, called a duchy, in Italy. It consists of three districts, viz. Parma, Piacenza, and Borgo St Domino, which, under the government of Napoleon, formed the department of the Taro, to which has been added the small duchy of Guastalla, now a fourth division. It is situated between Modena, the Austrian territory of Mantua, and the river Po, extends over 2266 square miles, and contains about 420,000 inhabitants, all of whom adhere to the Roman Catholic church. The district is generally a level plain, and part of it belongs to that of Lombardy. A portion of the Apennines is within the duchy, but it includes none of the higher elevations of that range of mountains. The Po, which is the northern boundary, receives the waters of the numerous small streams which, rising in the Apennines, serve the purpose of irrigation, and give fertility to the soil. The land is generally farmed on the metayer system, and the succession of crops is generally as follows: In the first year a fallow, with tobacco, maize, or hemp, well manured; in the second year rye; in the third beans; in the fourth wheat, manured; in the fifth clover; and in the sixth corn of some kind. More grain is produced than suffices for consumption, and abundance of flax, tobacco, and maize is exported, as well as fruit, wine, and olive oil. Silk is also produced in great abundance. The greatest profit of the husbandry of Parma is derived from the cattle. The cows are numerous, and of an excellent race; and the cheese as well as the butter produced yield large gains. The sheep are numerous, their flesh is good, and many of them yield the finest wool. There are mines of copper and of iron worked; and the several articles composed of these metals are manufactured within the duchy. Marble and alabaster are drawn from the quarries. Abundance of mineral oil is furnished from springs, and is used not only for greasing wheels of carriages, but for lighting the streets. There are few manufactures, and those which do exist are upon a small scale, and for domestic use. The government is monarchical, and is at present vested in Maria Louisa, the wife of Napoleon, but after her demise it will descend to the Duchess of Lucca. The revenues of the duchy amount to L.187,000. The military force consists of 3600 men, but only one third of them is in service at the same time.

PARMA, the capital of the duchy of that name, is a city situated on the river Parma, which divides it into two parts, and stands about three hundred feet above the level of the sea. It is surrounded with walls and ditches, protected by bastions, and it has also a citadel; but the fortifications are scarcely tenable against a serious attack. It is well built, and has broad, well-paved streets, with large palaces and houses; but few of them display much architectural taste, and even the ducal residence is not elegantly constructed. The opera-house is distinguished by its size; and some of the churches are large and magnificent. There is a university of ancient celebrity, an episcopal seminary, and a college for nobility. The inhabitants depend on their estates or on the court, and amount to 28,750 persons. Long. 10. 15. 14. E. Lat. 44. 48. 1. N.

PARMIGIANO, a celebrated painter, whose true name was Francesco Mazzuoli; but he received that of Parmigiano from the city of Parma, where he was born in 1504. He was brought up under his two uncles, and was an eminent painter when but sixteen years of age. He was famous all over Italy at nineteen; and at twenty-three he performed such wonders, that when the general of the Emperor Charles V. took Rome by storm, some of the common soldiers, having broken into his apartments, found him intent upon his work, and were so struck with the beauty of his pieces, that instead of involving him in the plunder and destruction in which they were then employed, they resolved to protect him from all manner of violence. His works are distinguished by the beauty of the colouring, the invention, and the drawing. His figures are spirited and graceful, particularly in respect to the choice of attitude, and the arrangement of drapery. He also excelled in music, in which he much delighted.

In large compositions Parmigiano did not always reach a high degree of excellence; but in his holy families, and other similar subjects, the gracefulness of his heads, and the elegance of his attitudes, are peculiarly remarkable. For the celebrity of his name he appears to have been chiefly indebted to his numerous drawings and etchings. As his life was short, and a great part of it consumed in the idle study of alchemy, and in the seducing avocations of music and gambling, but little time remained for application to the laborious part of his business. His paintings in oil are few in number, and held in high esteem; as are likewise his drawings and etchings. Good impressions of the last, however, are very rarely to be found. He was the first who practised the art of etching in Italy; and probably he did not at first know that it had been for some years practised in Germany. His principal works are at Parma, where he died poor in 1540.

PARNASSUS, a mountain of Phocis, near Delphi, with two tops; the one sacred to Apollo, the other sacred to Bacchus. It is thus described by Chandler:—"Parnassus was the western boundary of Phocis, and, stretching northward from about Delphi toward the Œtæan Mountains, separated the western Locri from those who possessed the sea-coast before Eubœa. It was a place of refuge to the Delphians in times of danger. In the deluge which happened under Deucalion, the natives were saved on it by following the cry of wolves. On the invasion by Xerxes, some transported their families over to Achaia, but many concealed them in the mountain, and in Corycium, a grotto of the Nymphs. All Parnassus was renowned for sanctity, but Corycium was the most noted among the hallowed caves and places. 'On the way to the summit of Parnassus,' says Pausanias, 'as much as sixty stadia beyond Delphi, is a brazen image; and from thence the ascent to Corycium is easier for a man on foot, and for mules and horses. Of all the caves in which I have been, this appeared to me the best worth seeing. On the coasts, and by the sea side, are more than can be numbered; but some are very famous both in Greece and in other countries. The Corycian cave exceeds in magnitude those I have mentioned, and for the most part may be passed through without a light. It is sufficiently high; and has water, some springing up, and yet more from the roof, which petrifies, so that the bottom of the whole cave is covered with sparry icicles. The inhabitants of Parnassus esteem it sacred to the Corycian nymphs, and particularly to Pan. From the cave to reach the summits of the mountain is difficult even to a man on foot. The summits are above the clouds, and the women called *Thyades* madden on them in the rites of Bacchus and Apollo.' Their frantic orgies were performed yearly. Wheler and his company ascended Parnassus from Delphi, some on horses, by a track between the stadium and the clefts of the mountain. Stairs were cut in the rock, with a strait channel, perhaps a water-duct. In a long hour, after many traverses, they gained the top, and entering a plain, turned to the right, towards the summits of Castalia, which are divided by deep precipices. From this eminence they had a fine prospect of the Gulf of Corinth, and of the coast; Mount Cirphis appearing beneath them as a plain, bounded on the east by the bay of Asprospitia, and on the west by that of Salona. A few shepherds had huts there. They returned to the way which they had quitted, and crossed a hill covered with pines and snow. On their left was a lake, and beyond it a peak, exceedingly high, white with snow. They travelled to the foot of it through a valley four or five miles in compass, and rested by a plentiful fountain called *Drosonigo*, the stream boiling up a foot in diameter, and nearly as much above the surface of the ground. It runs into the lake, which is about a quarter of a mile distant to the south-east. They did not discover Corycium, or proceed farther on, but keeping the lake on their right, came again to the brink of the mountain, and descended by a deep and dangerous track to Racovi, a village four or five miles eastward from Delphi. It was the opinion of Wheler, that no mountain in Greece was higher than Parnassus; that it was not inferior to Mont Cenis amongst the Alps; and that, if detached, it would be seen at a greater distance than even Mount Athos. The summits are perpetually increasing, every new fall of snow adding to the perennial heap, whilst the sun has power only to thaw the superficies. Castalis, Pleistus, and innumerable springs are fed, some invisibly, from the lakes and reservoirs, which, without these drains and subterraneous vents, would swell, especially after heavy rains and the melting of snow, so as to fill the valleys, and run over the tops of the rocks down upon Delphi, spreading wide an inundation, similar, as has been surmised, to the Deucalionian deluge."

PARNELL, Dr Thomas, an ingenious divine and an elegant poet. He was archdeacon of Clogher, and the intimate friend of Pope, who published his works, with a copy of recommendatory verses prefixed. He died in 1718, at the age of thirty-nine. "The life of Dr Parnell," says Johnson, "is a task which I should very willingly decline, since it has been lately written by Goldsmith, a man of such variety of powers, and such facility of performance, that he always seemed to do best that which he was doing; a man who had the art of being minute without tediousness, and general without confusion; whose language was copious without exuberance, exact without constraint, and easy without weakness. What such an author has told, who would tell again? I have made an extract from his larger narrative; and shall have this gratification from my attempt, that it gives me an opportunity of paying due tribute to the memory of a departed genius.

Το γαρ γερας ἐστι θανοντων.

"The general character of Parnell is not great extent of comprehension, or fertility of mind. Of the little that appears, still less is his own. His praise must be derived from the easy sweetness of his diction. In his verses there is more happiness than pains; he is sprightly without effort, and always delights though he never ravishes; everything is proper, yet everything seems casual. If there is some appearance of elaboration in the Hermit, the narrative, as it is less airy, is less pleasing. Of his other compositions, it is impossible to say whether they are the productions of nature so excellent as not to want the help of art, or of art so refined as to resemble nature."

PARNELLA, a town and district of Hindustan, in the province of Bejapoor, and one of the most healthy in the Mahratta dominions. Long. 74. 15. E. Lat. 16. 50. N. It was at this place that Aurungzebe's camp was stationed in April 1701, when Sir W. Norris, the ambassador from the English East India Company, arrived to treat with him.

PARO, more properly Beni, a great river of South America, and one of the three principal streams which form the famous Madera. Of these, the Paro is the first or most western branch. It is formed of an infinite number of smaller streams, which, falling into it within a short distance of each other, soon constitute a very considerable body of water. They have their sources in the mountains of Pelechuco, Suches, Sorata, Challana, Songa, La Paz, Suri, and Cochabamba, which ranges form part of the snowy cordillera visible from the city of La Paz. The farthest to the west is the Tuche; then follow the Aten, the Mapiri or Sorata, and the rivers which, descending from the celebrated mines of Tipuani, from Challana and from Coroico, afterwards unite; then the Chulumani and its tributary streams, the Taniampaya, the Solacama, the Rio de la Paz, the Suri, and the Canamena; and, last of all, there is the Cotacajes. Owing to the rapidity with which these currents descend from the cordillera, their navigation is difficult and dangerous; but the Indians display such dexterity in the management of their balsas or rafts, that the traveller has nothing to fear. Below Reyes, in about 12½° of south latitude, the Paro receives various other streams from the west, as the Tequeje, the Masisi or Cavinas, and others. From its junction with the Marmore, in about 10° south latitude, both rivers lose their names in that of the Madera. The course of the Paro lies between 10° and 17° 30′ of south latitude. It waters the whole of the district of Mosetenes, skirts the province of Moxos, and pursues its north-easterly course to the Marmore, through a fine level country. It would be extremely easy to unite the Beni with the Marmore, by means of the river Yacuma, which rises near Reyes, situated on the eastern bank of the Beni, and running eastward through the flat country between them, falls into the Marmore close to the town of Santa Anna. The fall of the land is so imperceptible, and so nearly on a level with the horizon, that it does not exceed twenty feet in a distance of more than sixty leagues. In the range of country traversed by the Paro, there is every variety of hill and dale, and plains with abundant smaller streams of running water. The vast and extensive levels along the banks offer the finest situations for agricultural establishments, and for the maintenance of a numerous population. The great fertility of the country is evinced by the extraordinary growth of the trees, and the innumerable plants which are spontaneously produced, affording sustenance and shelter to a prodigious variety of the animal creation. The best lands are principally occupied by the Mosetenes Indians, who give their name to the country where they chiefly reside. About Reyes are the Maropas tribe of Indians; lower down are the Pacaquaras, and there are a number of others which do not require to be particularly mentioned. (R. R. R.)

PARODY, a poetical pleasantry, consisting in applying the verses written on one subject, by way of ridicule, to another; or in turning a serious work into burlesque, by affecting to observe, as nearly as possible, the same rhymes, words, and cadences, in treating a mean, low, or ridiculous one.

The parody was first introduced by the Greeks, from whom the name has been borrowed. It comes pretty near to what some of the modern writers call *travesty*. Others, however, have more accurately distinguished between a parody and burlesque, observing, that the change of a single word may parody a verse, or that of a single letter a word. Thus, in the case of a word, Cato exposed the inconstant disposition of Marcus Fulvius Nobilior, by changing Nobilior into Mobilior. Another kind of parody consists in the mere application of some known verse, or portion of a verse, in a writer, without making any change in it, with a view to expose it. A fourth instance is that of writing verses in the taste and style of authors little approved. The rules of parody regard the choice of a subject, and the manner of treating it. The subject should be a known and celebrated work; and as to the manner, it should be an exact imitation, with an intermixture of good-natured pleasantry.

PAROLE, in a military sense, the promise made by a prisoner of war, when he has leave to go anywhere, of returning at a time appointed, if not exchanged.

PAROLE means also a word given out every day in orders by the commanding officer, both in camp and in garrison, for the purpose of distinguishing friends from enemies.

PARONOMASIA, in *Rhetoric*, a pun, or a figure, by which words nearly alike in sound, but of very different meanings, are affectedly or designedly used.

PAROS, an island belonging to the Turkish empire, in the Ægean Sea. It is separated by a narrow channel from Noxia on the eastern, and from Antiparos on the western side. It extends over 104 square miles, and contains about 2000 inhabitants. It is naturally fertile, but, by the conduct of the government, the population, mostly Greeks, are very much impoverished; and there is also a scarcity of water. The chief town is Parichia, situated on the western coast, with a good haven, and about 700 inhabitants. It was once celebrated for its marbles. Long. 19. 15. E. Lat. 42. 45. N.

PARPARSARAT, an island in the Eastern Seas, near the coast of Sumatra, and in the Straits of Malacca. It is fifty miles in circumference. Long. 102. 15. E. Lat. 1. 21. N.

PARR, CATHARINE, queen of England, was the eldest daughter of Sir Thomas Parr of Kendal. She was first married to John Nevil, Lord Latimer, and after his death was, by her marriage with Henry VIII., raised to the throne. The royal nuptials were solemnized at Hampton Court on the 12th of July 1543. This lady, being religiously disposed, was, in the early part of her life, a zealous observer of the rites and ceremonies of the Catholic Church; but on the dawning of the Reformation, she became as zealous a promoter of the Lutheran doctrine, though with all the prudence and circumspection which her perilous situation required. Nevertheless, it is alleged that she was in great danger of falling a sacrifice to the popish faction, the chief of which was Bishop Gardiner, who is said to have drawn up articles against her, and prevailed on the king to sign a warrant to remove her to the Tower. This warrant, however, was accidentally dropped, and immediately conveyed to her majesty. What her apprehensions must have been on making such a discovery may be easily imagined. Knowing the character of the monarch, and recollecting the fate of his former queens, she was seized with a sudden illness. The news of her indisposition brought the king to her apartment. He was lavish in expressions of affection, and sent her a physician. His majesty also being soon afterwards indisposed, she prudently returned the visit. With this the king seemed pleased, and began to talk with her on religious subjects, proposing certain questions, concerning which he wanted her opinion. She answered, that such profound speculations were not suited to her sex; that it belonged to the husband to choose principles for his wife; that the wife's duty was, in all cases, to adopt implicitly the sentiments of her husband; and that as to herself, it was doubly her duty, being blessed with a husband who was qualified, by his judgment and learning, not only to choose principles for his own family, but for the most wise and knowing of every nation. "Not so, by St Mary," replied the king; "you are now become a doctor, Kate, and better fitted to give than receive instruction." She meekly replied, that she was sensible how little she was entitled to these praises; that although she usually declined not any conversation, however sublime, when proposed by his majesty, she well knew that her conceptions could not serve any other purpose than to give him a little momentary amusement; that she found the conversation a little apt to languish when not revived by some opposition, and she had ventured sometimes to feign a contrariety of sentiments, in order to give him the pleasure of refuting her; and that she also proposed, by this innocent artifice, to engage him into topics, whence she had observed, by frequent experience, that she reaped profit and instruction. "And is it so, sweetheart?" replied the king; "then we are perfect friends again." He embraced her with great affection, and sent her away with assurances of his protection and kindness.

The time being now come when she was to be sent to the Tower, the king, walking in the garden, sent for the queen, and met her with great good humour; when the chancellor, with forty of the guards, approached. He fell upon his knees, and spoke softly with the king, who called him knave, arrant knave, beast, fool, and commanded him instantly to depart. Henry then returned to the queen, who ventured to intercede for the chancellor: "Ah, poor soul," said the king, "thou little knowest how ill he deserveth this grace at thy hands. Of my word, sweetheart, he has been toward thee an arrant knave; and so let him go." The king died in January 1547, just three years and a half after his marriage with this second Catharine, who, in a short time, was again espoused to Sir Thomas Seymour, lord-admiral of England; and in September 1548 she died in childbed. The historians of this period generally insinuate that she was poisoned by her husband, to make way for his marriage with the lady Elizabeth.

Catharine Parr wrote, 1. Queen Catharine Parr's Lamentation of a Sinner, bewailing the ignorance of her blind life, London, 1548, 1563, in 8vo; 2. Prayers or Meditations, wherein the mind is stirred patiently to suffer all afflictions here, to set at nought the vain prosperity of this world, and always to long for the everlasting felicity, printed by John Wayland, 1545, 4to, reprinted 1561, 12mo.

PARR, SAMUEL, a critic, metaphysician, theologian, and one of the most learned classical scholars of the age in which he lived, was born at Harrow-on-the-Hill, on the 15th of January 1747, O. S. His father, an apothecary and surgeon at Harrow, was equally distinguished by vigorous intellect, a spirit of manly independence, and great professional skill.

At Easter 1752, young Parr was admitted on the foundation of Harrow School, at that time conducted by the Rev. Dr Thackeray, and, for a long series of years, one of the most celebrated and successful of those great classical seminaries the pupils of which have contributed so largely to shed unparalleled lustre on the English name. That schools and universities can but initiate their pupils in the principles of literature and science, and ought not, perhaps, to aim at more, it would be unwise to dispute.

That those pre-eminent geniuses who have, in all ages of the world, enlarged the field of science by their discoveries, or embellished literature by their taste, have owed their success and reputation to their native talents and persevering industry, may without scruple be admitted as established facts in the history of the human mind. Still, it is a truth no less capable of demonstration, that in most instances the *primary* causes of great eminence and high attainment in the pursuits of life may be traced to the impulse given by the teacher's well-directed precepts, and the mutual collision of kindred minds in the strife of early competition. It may fairly be assumed, that, to the rare combination of these circumstances operating on a mind essentially powerful and capacious, Parr was in no ordinary degree indebted for his extensive scholarship and well-earned fame. When we find that Thackeray and Sumner were his instructors, and that such men as Sir William Jones, and Dr Bennet, bishop of Cloyne, were his schoolfellows and inseparable companions, we are naturally and easily prepared to anticipate, even in this early period of his intellectual career, an energetic development of those powers of thought which, in the progress of life, unfolded themselves with almost unexampled force and vigour. At the early age of fourteen, he had by his diligence and talents gained the approbation of his successive teachers; and, in January 1761, he became the head boy of the school. The elevated rank which he thus held amongst his school-fellows clearly indicates how thoroughly and effectively he devoted himself to those classical studies in which, to the latest years of his life, he felt such intense delight. But to these, even at this period of his life, his time and attention were not exclusively confined. Before he had completed his course of scholastic training at Harrow, though metaphysics and dialectics offer but few attractions to the mind of boyhood, he had made no inconsiderable proficiency in these branches of mental science, and had maintained upon subjects connected with them many a friendly conflict with the generous rivals of his honours and partners of his studies. These prolusions of juvenile genius and talent were not a useless display of intellectual gladiatorship, or unaccompanied with improvement to the youthful combatants. The faculties of the mind, like the powers of the body, are invigorated by frequent exercise, and only attain their full development in point of energy and capacity by the excitement of generous and salutary competition.

In 1761, Parr, having completed the course of study pursued at Harrow, left school, and was, for two or three subsequent years, employed by his father in his own profession. But though the duties in which he was thus necessarily engaged occupied much of his time, and were calculated in some degree to withdraw his attention from the studies of earlier years, his classical pursuits were never entirely suspended, nor did his ardent devotion to Greek and Roman literature experience any abatement or change. It was not to be expected that one whose taste was so exquisitely alive to the beauties of the classic page, would apply with equal warmth of interest to the compounding of medicines, and the other duties of the laboratory, or regard as any thing else than an irksome task the manipulations of a profession which was so little congenial to his aspirations and desires.

Determined by such unequivocal proofs of his decided predilection for literary pursuits and academical studies, his father, after considerable hesitation, resolved at last to accommodate his views to the wishes of his son, and in 1765 entered him at Emanuel College, Cambridge. In this noble arena of mental activity, where all was in harmony with his most eager wishes, his application to study was enthusiastic, incessant, and severe. Classical reading, mathematics, and those subsidiary but indispensable investigations by which a thorough knowledge of these subjects is acquired and established, were pursued, not merely for their own sake, but as opening up to their successful cultivator the sure path to academical honours and distinction. These exciting and pleasing prospects, however, were not destined to be realized. The inadequacy of the means necessary for his longer continuance at Cambridge, in consequence of his father's death, induced him gratefully to accept the proposal made to him by Dr Sumner, to take the vacant place of first assistant in Harrow School.

At Christmas 1769 he was ordained to the curacies of Willsden and Kingsbury, in Middlesex, the duties of which, in conjunction with those proper to the situation which he held in the school, he continued to discharge till the death of Dr Sumner in 1771. In Dr Sumner he found a faithful friend and counsellor, and gave such satisfaction to the pupils and their parents, that, on the occurrence of this vacancy of the head-mastership of Harrow School, he felt himself called upon to become a candidate, and was on every ground justified in making such an application. He was unsuccessful; the election fell on Dr Heath, an assistant at Eton, whose merit and success amply justified the choice of the governors. He so far resented this decision in favour of the successful candidate, as to resign his assistantship, and open a school at Stanmore, to which he was, from affectionate attachment, followed by forty of the pupils whom he had taught at Harrow.

The success of this undertaking, however, corresponded but ill with the auspicious beginning that ushered it in; and a variety of circumstances concurred, of such a nature as to recommend the propriety of a change of situation, and to render it desirable. Influenced, accordingly, by these considerations, he became a candidate for the school of Colchester, and having succeeded in attaining the appointment, he went to reside there in 1777. During his residence at Colchester he took priest's orders, and his curacies were Hythe and Trinity Church.

In 1778, he obtained the appointment of head-master of Norwich School, and early in 1779 entered upon the duties of his office. In the following year he published his two sermons, "On the Truth and Usefulness of Christianity," and "On the Education of the Poor." He afterwards, in 1785, resumed the subject of the latter at greater length, in his "Discourse on Education, and on the Plans pursued in Charity Schools." This was the most popular of all his writings, and is a conspicuous and noble monument of its gifted author's enlarged views, pure benevolence, and deep insight into human character. The general education of the people in any nation, and still more the extension of its advantages and blessings to the whole human race, are subjects on which the genuine philanthropist and truly enlightened Christian dwell with delight and rapture. And in what, indeed, can the friend of his fellow-men more worthily employ his time and talents, than in promoting those comprehensive schemes which aim, not at the elevation of one class of men above another in worldly dignity and grandeur, nor at the temporary glory and exaltation of any single nation or race of men, but at raising higher in the scale of intelligence and happiness all of every tribe on whom the Common Parent has bestowed the capacity of mental, moral, and religious culture? This has since become in Great Britain a national and engrossing topic; theory and practice have mutually and equally contributed their aid to the advancement of national and universal education; and he who, half a century before his death, advocated with such ability and power the cause of the poor and ignorant, had the felicity to witness the dawn of that brighter era in the history of mankind, the meridian effulgence of which must precede or accompany the universal diffusion of pure religion and divine truth. These elaborate and masterly discourses, elucidating, as they do, a subject of permanent and incalculable interest, will always be perused with admiration and benefit. They will extend the reader's information, and improve his heart. They are pervaded and beautified by a deep tone of fervent piety, and breathe the warmest wishes for the intellectual, moral, and spiritual interests of the great family of man.

In 1781, Parr took his degree of doctor of laws in the University of Cambridge, after supporting two theses, which were regarded as compositions of superior excellence and merit. In 1783, he was by Dr Robert Lowth, bishop of London, appointed one of the prebends of St Paul's cathedral. The duties of this office were nearly nominal, but its revenues afforded him the means of comfort and independence during the remainder of his life. In 1783, he was presented by Lady Jane Trafford to the perpetual curacy of Hatton, Warwickshire, to which, after resigning the school at Norwich, he went to reside in 1786. Here he continued to devote his leisure to the tuition of a limited number of pupils; and, by making it his permanent residence to the end of his life, he bequeathed to it that celebrity and interest which any locality, however obscure, necessarily and justly derives from the fame of an illustrious inhabitant.

In 1787 appeared the justly celebrated preface to Bellendenus, of which Henry Homer, fellow of Emanuel College, Cambridge, was editor. Bellenden, the author, was a learned Scotchman, master of requests to James I., and professor of humanity at Paris in the beginning of the seventeenth century. The three books of Bellendenus are in this edition dedicated to Mr Burke, Lord North, and Mr Fox. The preface by Dr Parr, which is prefixed to the original work of Bellenden, delineates, in elegant and vigorous language, the characters of the three distinguished statesmen to whom the respective books are dedicated. This singularly felicitous composition, though too slavishly and undisguisedly a *cento*, is undeniably one of the most successful modern imitations of Ciceronian Latin. But the highly embellished eloquence and precise discrimination of character, which give such value to this masterly declamation, can never be accepted as a compensation or atonement for the rude sarcasm, the contemptuous and unmeasured virulence, with which he assails, unprovoked, the devoted objects of his political vengeance. This extraordinary production was read with avidity, and created a very uncommon sensation amongst the men of letters and politicians of the day. It was productive, however, of no effects beneficial to the author; and alienated from him, in all probability, the minds of many who would otherwise have proved friendly or indifferent. Even the statesmen whom he had so lavishly and eloquently panegyrised, when they reached the summit of power, and became dispensers of ecclesiastical honours and emoluments, granted him no promotion; and his warmest friends have seriously deplored the employment of his talents in a manner so inconsistent with his sacred character. It is a matter of deep regret that he should have so far extinguished in his breast the meek and gentle spirit of that religion, the peaceful and holy duties of which he was bound, equally by precept and example, to impress on the hearts and consciences of men.

The generosity of his nature, and his readiness to oblige, by giving a real or supposed friend the benefit of his great talents, brought him oftener than once into unhappy collision with inferior men, who scrupled not to arrogate importance to themselves, by laying claim to compositions in the merits and excellence of which they were in reality entitled to but a secondary and subordinate share. In 1790, we find him involved in an obscure and intricate controversy of this kind respecting the authorship of the Bampton Lectures, published by Dr White. It would be an uninstructive and fruitless deviation from the conciseness necessary to be observed in this biographical outline, to enter fully into the merits of this dark transaction; but the letters published by Dr Johnson, in his memoirs of Parr's life and writings, have clearly established the fact, that much of the talent displayed in these admirable compositions, if not the conception of the whole work, must in justice be ascribed to the transcendent energy of Parr's capacious mind. On the contrary, White, Badcock, and the other individuals who make a figure in this discreditable controversy, stand convicted, upon satisfactory evidence, of mean and ungrateful plagiarism.

The "Tracts by Warburton and a Warburtonian, not admitted into the collection of their respective works," appeared in 1789, with a dedication addressed by the editor to a learned critic, containing some excellent critical remarks, and abounding at the same time in forcible expression and happy illustration. Of this composition Warton, no mean authority, is reported to have said, that if he were called upon to point out some of the finest sentences in English prose, he would quote Parr's Preface and Dedication of the Warburtonian Tracts.

The tremendous explosion in France, of that revolutionary volcano which seemed to threaten the world with a total dislocation of civilized society, made the shock be felt in every region of the earth. The immediate vicinity of Britain to the scene of this great convulsion, exposed her population in a peculiar degree to the danger of being involved in all the terrific consequences of a similar catastrophe. The inhabitants of this island had long claimed and enjoyed, as their inalienable birthright, the most unlimited freedom of thought, speculation, expression, and action. In a country so situated and so circumstanced, therefore, it was not to be conceived or expected that the movements of so vast a revolution would not receive from some the most sympathising admiration, whilst by others they would be contemplated with horror and repugnance. And whilst every member of the great British commonwealth discussed, with all the confidence of the most profound and enlightened statesman, such subjects as policy, government, the rights, natural or acquired, of individuals and communities, and all else that concerns the great destinies of man as a member of social life, it was not to be expected that Dr Parr alone would remain apathetic and unmoved amidst the heats and conflicts of political controversy by which he was surrounded. But although every action of his long life proves him to have been the steady and consistent advocate of freedom, he was too well acquainted with the history of democracy in all its modifications, and in every age, to favour its pretensions, or lend the aid of his great talents to the support of its excesses and extravagance. Parr was no Jacobin. He was a decided, sincere, unflinching Whig, and in principle a firm supporter of the constitutional liberties of Britain. He was not, however, of a temper to disguise his opinions on any subject in which he felt and took an interest; and accordingly he sometimes expressed himself with such boldness and freedom on questions of civil policy, that he incurred the imputation of regarding with favour and partiality the doctrines promulgated and acted upon by the republican revolutionists of France. As the alleged abettor of such principles, he was about this period of his life exposed to assaults, on the assumed ground that he was guilty of political delinquencies, which his life disproves and his writings disavow.

Parr shunned neither churchman nor dissenter who was unblemished in character and eminent in talents. With Dr Priestley, amongst others, he had exchanged civilities; and when the library and philosophical apparatus of the latter were in 1791 consigned to destruction by the Birmingham rioters, the knowledge that such intercourse had subsisted between them prompted the infuriated mob to regard both as holding and professing the same common principles and sentiments. Under the influence of this dangerous delusion, they threatened to commit Dr Parr's house and library also to the flames, and manifested so decided a determination to carry their threats into execution, that it was judged a necessary precaution to remove the books to a place of safety. Before, however, the incendiaries were able to put their design in execution, their proceedings were checked by the seasonable interposition of the military. Of these riots a durable record is preserved in the "Sequel to the printed Paper lately circulated in Warwickshire, by the Rev. Charles Curtis, brother of Alderman Curtis, a Birmingham Rector, London, 1792;" of which the preface is justly admired as one of the most perfect specimens of the author's composition in his best and most laboured style. A prevalent rumour that the dissenters in the following year meditated a meeting in commemoration of the French Revolution, similar to that which had led to and provoked the riots of the preceding year, occasioned the hasty composition and publication of "A Letter from Irenopolis to the Inhabitants of Eleutheropolis; or, a Serious Address to the Dissenters of Birmingham;" a tract which, in elegance, perspicuity, and vigour, may safely stand a comparison with the most finished and elaborate of his former writings. The dissenters immediately published a declaration, in which they disclaimed all intention of holding such a meeting as the reports currently circulated had given reason to expect.

In 1793, Parr, who it seems had with disinterested kindness afforded gratuitously considerable assistance to his friend Homer in preparing for the press the variorum edition of Horace in which he was engaged, was, upon the death of the original editor, hurried into a painful controversy with Dr Combe, who prosecuted the work to its completion. After Homer's death, Dr Parr, for some reason which has not been very clearly ascertained, not only withheld his countenance and assistance, but published a series of severe animadversions upon the work, in several numbers of the British Critic. Dr Combe published in reply a pamphlet, entitled "A Statement of the Facts relative to the Behaviour of the Rev. Dr Parr to the late Mr Homer and Dr Combe, in order to point out the source, falsehood, and malignity of Dr Parr's attack, in the British Critic, on the character of Dr Combe, 1794." The opprobrious and highly offensive terms emblazoned on the title-page of this tract were calculated to rouse the indignation of the meekest spirit, and could not with propriety and a sense of self-respect be allowed, unanswered, to infuse their venom into and corrupt the public mind. Dr Parr was neither insensible to the language of petulance and scorn, nor was his temper such as to submit tamely and in silence to outrage and abuse. He might indeed say with truth,—

> Qui me commôrit (melius non tangere, clamo)
> Flebit, et insignis tota cantabitur urbe.

Accordingly, he replied in a pamphlet, bearing the title, "Remarks on the statement of Dr Charles Combe, by an occasional writer in the British Critic, 1795." It is written in a temperate, calm, and guarded tone; the sarcastic asperity of its author might have inflicted, and the provocation would have justified, a much severer castigation than the rash delinquent was doomed to endure.

In the year 1800, by the appointment of Mr Alderman Combe, lord mayor of London, Dr Parr preached the celebrated Spital sermon in Christ-Church. Capacious as the building is, it was crowded to excess by an intelligent audience, who, for nearly two hours, listened with the most profound attention to the speaker's convincing arguments and resistless eloquence. This elaborate discourse may be regarded as a continuation and extension of those in which he had previously with great ability advocated the cause of general education; and in the course of it the author combats, with irresistible effect, the delusive metaphysics of those philosophers who resolve benevolence and justice into the principle of selfishness. Soon after its delivery, this very original and almost unrivalled composition was printed and published, exhibiting the extraordinary proportion of fifty-one pages occupied with text, and 212 with notes. It called forth some observations from Mr Godwin, the author of "Political Justice," in an octavo pamphlet, entitled "Thoughts occasioned by the perusal of Dr Parr's Spital Sermon, being a reply to Dr Parr, Mr Mackintosh, and others." The author of this tract, who knew as well as any man could do Dr Parr's political leanings and opinions, states in one sentence, written whilst his mind was soured by displeasure and chagrin, what is quite sufficient to refute the charge too often made, and too readily believed, that he was the abetter of revolutionary and democratic principles. "I have always found him," says Mr Godwin, "the advocate of old establishments, and, what appeared to me, old abuses." Parr was ardently desirous to see the condition of mankind meliorated by gradual improvements in their civil and social condition; but he was at the same time, in all its interests, a warm admirer of the British constitution in church and state.

In 1802, Sir Francis Burdett presented him to the rectory of Graffham in Huntingdonshire. The generosity which the baronet exhibited on this occasion is highly creditable to his character, and the value of the gift to the receiver of it must have been immeasurably enhanced by the fine tact and delicacy with which it was conferred. In the letter in which he makes the unsolicited offer, he observes, that a great motive to make it was, that he believed he could do nothing more pleasing to his friends, Mr Fox, Mr Sheridan, and Mr Knight; thus making the appointment in a great measure a favour conferred by those personal friends whom Parr most highly esteemed. Nor is the allusion in his reply to the part of Burdett's letter just referred to less honourable to the author's heart. "Most assuredly I shall myself set a higher value upon your kindness, when I consider it as intended to gratify the friendly feelings of those excellent men, as well as to promote my own personal happiness." He continued, however, to reside at Hatton, where he was greatly esteemed by his parishioners, and had made such additions to his house as to render it peculiarly suited to his convenience and wishes.

On the renewal of the war with France in the year 1803, he published his sermon, "preached on the late fast, October 19, at the parish church of Hatton." It is a noble discourse, well calculated to rouse his hearers, and the nation generally, to heroic and determined resistance against the threatened invasion by the French.

His next publication, and the last that is entitled to particular notice, "Characters of the late Charles James Fox, selected, and in part written, by Philopatris Varvicensis," appeared in 1809. It consists partly of extracts from the various public journals, and is partly of an original character, addressed in the form of an epistle to Mr Coke, with an additional volume of notes. This work, in which the great statesman, his principles and powers of mind, are delineated with much beauty and effect, remains a noble monument of his worth, and of the talents and warm affection of his devoted and enthusiastic panegyrist.

Dr Parr was twice married; in 1771 to Miss Jane Marsingale, who died on the 9th of April 1810; and again, in 1817, to Miss Eyre, sister of the Reverend James Eyre of Coventry. Of his children, one died at Norwich, and another, Catherine, fell a victim to consumption at Teignmouth in 1805. A third, Sarah, was married to Mr Wynne of Plasnewydd, Denbighshire, but she also died early.

In 1823, his strength began visibly to decline; and his spirits ceased to display their wonted elasticity and animation. On Sunday the 16th of January 1825 he performed all the duties of the church at Hatton; but was, in the course of the following night, seized with severe fever and delirium. From that period his vital powers gradually declined; but he bore his sufferings with patient fortitude and pious resignation; and on the evening of Sunday the 6th of March 1825 gently expired, having on the 26th of January completed the seventy-eighth year of his age. His remains were deposited in a vault of Hatton Church; and Dr Butler, archdeacon of Derby, and head master of Shrewsbury School, preached the funeral sermon, from the text which Dr Parr had directed to be inscribed on his monument: *What doth the Lord require of thee, but to do justly, and to love mercy, and to walk humbly with thy God?*

Dr Parr was endowed by nature with a powerful intellect and retentive memory; in argument he was keen and irresistible; but he was opinionative, strong in his likings and aversions, and impatient of opposition. In politics he displayed the most ardent love of freedom, the most incorruptible integrity, and resolute independence. In learning he was perhaps unrivalled by any other individual of the age in which he lived; as a classical scholar he was not surpassed; he excelled in metaphysics and moral philosophy; and in theology he had read extensively and thought deeply. Benevolence and charity, especially to young men of promising talents, whose means were inadequate to their support, were pre-eminent qualities of his frank and generous heart. He was full of truth and integrity, and his piety, though unostentatious, was fervent and sincere. (A. R. C.)

Parr, *Thomas*, a remarkable Englishman, who lived in the reigns of ten kings and queens, and having married a second wife when he was 120, had a child by her. He was the son of John Parr, a husbandman of Winnington, in the parish of Alderbury, in the county of Salop, where he was born in the year 1483. Though he lived to the great age of upwards of 152 years, yet the tenor of his life admitted of but little variety; nor can the detail of it be considered as of importance, further than what may arise from the gratification of that curiosity which naturally inquires after the mode of living which could lengthen life to such extreme old age. Following the profession of his father, he laboured hard, and lived on coarse fare. Taylor, the water poet, says of him:

> Good wholesome labour was his exercise,
> Down with the lamb, and with the lark would rise;
> In mire and toiling sweat he spent the day,
> And to his team he whistled time away:
> The cock his night-clock, and, till day was done,
> His watch and chief sun-dial was the sun.

And the same writer observes of him, that

> From head to heel, his body had all over
> A quick set, thick set, natural hairy cover.

The manner of his being conducted to London is also noticed in the following terms: "The Right Honourable Thomas earl of Arundel and Surrey, earl marshal of England, on being lately in Shropshire to visit some lands and manors which his lordship holds in that county, or for some other occasions of importance which caused his lordship to be there, the report of this aged man was signified to his honour; who hearing of so remarkable a piece of antiquity, his lordship was pleased to see him; and in his innate, noble, and Christian piety, he took him into his charitable tuition and protection, commanding that a litter and two horses (for the more easy carriage of a man so feeble and worn with age) to be provided for him; also, that a daughter of his, named Lucy, should likewise attend him, and have a horse for her own riding with him; and to cheer up the old man, and make him merry, there was an antique-faced fellow, with a high and mighty nobeard, that had also a horse for his carriage. These were all to be brought out of the country to London by easy journeys, the charge being allowed by his lordship; likewise one of his lordship's own servants, named Bryan Kelly, to ride on horseback with them, and to attend and defray all manner of reckonings and expenses." All this was accordingly done.

"Winnington is a parish of Alderbury, near a place called the Welch Pool, eight miles from Shrewsbury; from whence he was carried to Wem, a town of the earl's aforesaid; and the next day to Shiffnall, a manor-house of his lordship's, where they likewise stayed one night: from Shiffnall they came to Wolverhampton, and the next day to Birmingham, and from thence to Coventry. Although Master Kelly had much to do to keep the people off that pressed upon him in all places where he came, yet at Coventry he was most oppressed, for they came in such multitudes to see the old man, that those who defended him were almost quite tired and spent, and the aged man in danger of being stifled; and, in a word, the rabble were so unruly, that Bryan was in doubt he should bring his charge no farther; so greedy are the vulgar to hearken to or gaze after novelties. The trouble being over, the next day they passed to Daintree, to Stony Stratford, to Radburne, and so to London; where he was well entertained and accommodated with all things, having all the foresaid attendance at the sole charge and cost of his lordship." When brought before the king, his majesty, with more acuteness than good manners, said to him, "You have lived longer than other men, what have you done more than other men?" He answered, "I did penance when I was a hundred years old." This journey, however, proved fatal to him. Owing to the alteration in his diet, the change of the air, and his general mode of life, he lived but a very short time; and having died on the 5th of November 1635, he was buried in Westminster Abbey. After his death, his body was opened; and an account of the *post mortem* examination was drawn up by the celebrated Dr Harvey.

"Thomas Parr," says that great physician, "was a poor country man of Shropshire, whence he was brought up to London by the Right Honourable Thomas earl of Arundel and Surrey; and died after he had outlived nine princes, in the tenth year of the tenth of them, at the age of 152 years and nine months.

"He had a large breast, lungs not fungous, but sticking to his ribs, and distended with blood; a lividness in his face, as he had a difficulty of breathing a little before his death, and a long lasting warmth in his armpits and breast after it; which sign, together with others, were so evident in his body, as they use to be on those that die by suffocation. His heart was great, thick, fibrous, and fat. The blood in the heart blackish and diluted. The cartilages of the sternum not more bony than in others, but flexile and soft. His viscera were sound and strong, especially the stomach; and it was observed of him, that he used to eat often by night and day, though contented with old cheese, milk, coarse bread, small beer, and whey; and, which is more remarkable, that he ate at midnight a little before he died. His kidneys were covered with fat, and pretty sound; only on the interior surface of them were found some aqueous or serous abscesses, whereof one was near the bigness of a hen egg, with a yellowish water in it, having made a roundish cavity, impressed on that kidney; whence some thought it came that a little before his death a suppression of urine had befallen him, though others were of opinion that his urine was suppressed upon the regurgitation of all the serosity into his lungs. Not the least appearance there was of any stony matter either in the kidneys or bladder. His bowels were also sound, a little whitish without. His spleen very little, hardly equalling the bigness of one kidney. In short, all his inward parts appeared so healthy, that if he had not changed his diet and air, he might perhaps have lived a good while longer. The cause of his death was imputed chiefly to the change of food and air; forasmuch as coming out of a clear, thin, and free air, he came into the thick air of London; and after a constant plain and homely country diet, he was taken into a splendid family, where he fed high and drank plentifully of the best wines, whereupon the natural functions of the parts of his body were overcharged, his lungs obstructed, and the habit of the whole body quite disordered; upon which there could not but ensue a dissolution. His brain was sound, entire, and firm; and though he had not the use of his eyes, nor much of his memory, several years before he died, yet he had his hearing and apprehension very well; and was able, even to the 130th year of his age, to do any husbandman's work, even thrashing of corn."

PARRELS, in a ship, are frames made of trucks, ribs, and ropes, which, having both their ends fastened to the yards, are so contrived as to go round the masts, that by their means the yards may move up and down upon the mast. The parrels also, along with the breast-ropes, fasten the yards to the masts.

PARRHASIUS, a celebrated painter, the son of Evenor, was a native of Ephesus, and flourished in the year 397 before Christ, being the contemporary of Zeuxis, Eupompus, and Timanthes. He was the first who succeeded in giving the proper proportion to his figures, in throwing the expression of the passions into the countenance, and in causing the figure to appear to start from the canvass. Several who had preceded him were successful in finishing particular parts, but none could rival him in putting the whole together. Zeuxis was the only one of his contemporaries who at all approached him, and even he was at last obliged to acknowledge his inferiority. (See Zeuxis.) One of his most curious paintings was a representation of the Demos of Athens, in which he had contrived to exhibit all the various passions with which that celebrated people were affected. His painting of the Hoplites, or the armed man running, had the effect of a person perspiring from excessive exertion; and another who was taking off his arms seemed to be panting for breath. Parrhasius was, like Zeuxis, distinguished for his vanity and arrogant mode of life. He used to wear a purple dress, a golden crown on his head, to hold in his hand a staff studded with golden nails, and to wear golden latchets to his shoes (Ælian. *Var. Hist.* ix. 11). He was once beaten by Timanthes, in the subject of Ajax disputing with Ulysses respecting the arms of Achilles (Plin. xxxv. 36, 7–11; Athen. xii. 543, e. d. xv. 687, b. c.).

Parrhasius, *Janus*, a famous grammarian in Italy, who was born at Cosenza, in the kingdom of Naples, in the year 1470. He was intended for the law, the profession of his ancestors; but he refused to pursue it, and cultivated classical learning. His real name was Johannes Paulus Parisius; but, according to the practice of the grammarians of the age, he took instead of it that of Parrhasius. He taught at Milan with much reputation, being admired for a graceful delivery, in which he chiefly excelled other professors. It was this charm in his voice which brought a vast concourse of people to his lectures; and, amongst others, he had the pleasure of seeing General Trimoles, who was then threescore years of age. He went to Rome when Alexander VI. was pope, and had nearly been involved in the misfortunes of Bernardini Cajetan and Silius Savello, with whom he had some correspondence; but he escaped the danger, by the information of Thomas Phœdrus, professor of rhetoric, and canon of St John Lateran, whose advice he followed by retiring from Rome. Soon afterwards, he was appointed public professor of rhetoric at Milan; but the liberty which he took in censuring the teachers there as arrant blockheads provoked them in return to asperse his morals. He, in consequence, went to Vicenza, where he obtained a larger salary; and he held this professorship till the states of the Venetians were laid waste by the troops of the League; upon which he went to his native country, having made his escape through the army of the enemy. He was at Cosenza when his old friend Phœdrus persuaded Julius to send for him to Rome; and although that design proved abortive by the death of the pope, yet, on the recommendation of John Lascaris, he was called thither under Leo X. the successor of Julius. Leo was before favourably inclined towards him, and on his arrival at Rome appointed him professor of polite literature. He had been now some time married to a daughter of Demetrius Chalcondylas; and he took with him to Rome, Basil Chalcondylas, brother of Demetrius Chalcondylas, professor of the Greek tongue at Milan. But he did not long enjoy the office which had been conferred upon him by the pope; for, worn out by his studies and labours, he became so afflicted with the gout, that for some years there was no part of his body unaffected except his tongue. He left Rome and returned to Calabria, his native country, where he at last died in the greatest misery. Several works have been ascribed to him.

PARRIAH, a town of Hindustan, in the province of Bahar, and district of Tirhoot. There was formerly a fort here, as a defence against the incursions of the natives from the northern hills. Long. 85. 52. E. Lat. 26. 41. N.

PARRICIDE, the murder of one's parents or children. By the Roman law, this crime was punished in a much more severe manner than any other kind of homicide. The delinquents, after being scourged, were sewed up in a leathern sack, with a live dog, a cock, a viper, and an ape, and were then cast into the sea. Solon, it is true, in his laws, made none against parricide, apprehending it impossible that any one could be guilty of so unnatural a barbarity; and the Persians, according to Herodotus, entertained the same notion, when they adjudged all persons who killed their reputed parents to be bastards.

PARROT Islands, a cluster of islands in Dusky Bay, New Zealand, three miles south-west from Facile harbour.

PARSON *and* Vicar, in the Church of England. A parson, *persona ecclesiæ*, is one who has full possession of all the rights of a parochial church. He is called parson, *persona*, because by his person the church, which is an invisible body, is represented; and he is in himself a body corporate, in order to protect and defend the rights of the church, which he personates, by a perpetual succession. He is sometimes called the *rector* or governor of the church; but the appellation of *parson*, however it may be depreciated by familiar and indiscriminate use, is the most legal and most honourable title that a parish priest can enjoy; because such a one, as Sir Edward Coke observes, and he alone, is said *vicem seu personam ecclesiæ gerere*. A parson has, during his life, the freehold in himself of the parsonage-house, the glebe, the tithes, and other dues. But these are sometimes appropriated; that is to say, the benefice is perpetually annexed to some spiritual corporation, either sole or aggregate.

The appropriating corporations, or religious houses, were wont to depute one of their own body to perform divine service, and administer the sacraments, in those parishes of which the society was thus the parson. This officiating minister was in reality no more than a curate, deputy, or vicegerent of the appropriator, and was therefore called *vicarius*, or vicar. His stipend was at the discretion of the appropriator, who was, however, bound of common right to find somebody, *qui illi de temporalibus, episcopo de spiritualibus, debeat respondere.* But this was done in so scandalous a manner, and the parishes suffered so much by the neglect of the appropriators, that the legislature was forced to interpose; and accordingly it was enacted, by statute 15 Richard II. c. 6, that in all appropriations of churches the diocesan bishop should ordain, in proportion to the value of the church, a competent sum to be distributed amongst the poor parishioners annually, and to provide that the vicarage should be sufficiently endowed. It seems that the parish were frequent sufferers, not only by the want of divine service, but also by the withholding of those alms for which, amongst other purposes, the payment of tithes was originally imposed; and therefore in this act a pension was directed to be distributed amongst the poor parochians, as well as a sufficient stipend to the vicar. But he, being liable to be removed at the pleasure of the appropriator, was not likely to insist too rigidly upon the legal sufficiency of the stipend; and, therefore, by statute 4 Henry IV. c. 12, it was ordained that the vicar should be a secular person, not a member of any religious house; that he should be vicar perpetual, not removeable at the caprice of the monastery; and that he should be canonically instituted and inducted, and be sufficiently endowed, at the discretion of the ordinary, to do divine service, to inform the people, and to show hospitality. In consequence of these statutes, the endowments have usually been by a portion of the glebe, or land belonging to the parsonage, and a particular share of the tithes, which the appropriators found it most troublesome to collect, and which are therefore generally called *petty* or *small tithes;* the greater, or predial tithes, being still reserved for their own use. But the same rule was not observed in the endowment of all vicarages. Hence some are more liberally, and others more scantily, endowed; and hence the tithes of many things, as wood in particular, are in some parishes rectorial, and in others vicarial, tithes.

The distinction therefore between a parson and vicar is this. The parson has for the most part the whole right to all the ecclesiastical dues in his parish; but a vicar has generally an appropriator over him, who is entitled to the best part of the profits, and to whom he is in effect perpetual curate, with a standing salary. The method of becoming a parson or vicar is much the same. To both there are four necessary requisites; holy orders, presentation, institution, and induction.

PARSONAGE, a rectory or parish church, endowed with a glebe, house, lands, and tithes, for the maintenance of a minister, with cure of souls within the parish.

PARSONAUTH, a town of Hindustan, in the province of Bahar, situated amongst the hills, between Bahar and Bengal. It is held in great estimation by the Jains, as a remarkably holy place. One of the principal deities is named Pariswanath, the real founder of the sect, who died at the age of a hundred years.

PART is a portion of a whole, considered as divided or divisible.

Logical Part is a division for which we are indebted to the schoolmen. It refers to some universal as its whole; in which sense the species are parts of a genus, and individuals or singulars are parts of the species.

Physical Part is that which, though it enter into the composition of a whole, may yet be considered apart, and under its own distinct idea; and in this sense a *continuum* is said to consist of parts. Physical parts, again, are of two kinds, homogeneous and heterogeneous. The first are those of the same denomination with some other; the second are of a different denomination. Parts, again, are distinguished into subjective, essential, and integrant; a division of which the schoolmen were likewise the authors.

Aliquot Part is a quantity which, being repeated any number of times, becomes equal to an integer. Thus 6 is an aliquot part of 24, and 5 an aliquot part of 30.

Aliquant Part is a quantity which, being repeated any number of times, becomes always either greater or less than the whole. Thus 5 is an aliquant part of 17, and 9 is an aliquant part of 10. The aliquant part is resolvable into aliquot parts. Thus 15, an aliquant part of 20, is resolvable into 10, a half, and 5, a fourth part, of the same number.

PARTALPOOR, a town of Bengal, in the district of Midnapoor. Long. 87. 50. E. Lat. 22. 21. N.

PARTANNA, a city of the intendency of Trapani, in the district of Mazzara, in the island of Sicily. It stands on a hill, about eight miles from the sea, in a healthy situation, fifty miles from Palermo, and contains 7100 inhabitants, employed in growing cotton wool, and in feeding black cattle.

PARTERRE, in *Gardening*, a level division of ground, which for the most part faces the south or best front of a house, and is generally furnished with evergreens, shrubs, and flowers.

PARTHENAY, an arrondissement of the department of the Two Sèvres, in France, extending over 683 square miles. It comprehends eight cantons, divided into forty-six communes, and containing 55,300 inhabitants. The capital is the city of the same name, situated on the river Thoué. It was one of the chief seats of the Vendean war, and suffered most severely. It contains 800 houses, and 3600 inhabitants. Long. 0. 19. W. Lat. 46. 40. N.

PARTHIA, a celebrated empire of antiquity, bounded on the west by Media, on the north by Hyrcania, on the east by Aria, and on the south by Caramania. It was surrounded on every side by mountains, which still serve as its boundaries, though the name is now changed. According to Ptolemy, Parthia was divided into five districts; Caminsine or Gamisene, Partheyne, Choroane, Atticene, and Tabiene. The ancient geographers enumerate a great many cities in this country. Ptolemy, in particular, reckons twenty-five large ones; and it must have been very populous, since we have accounts of two thousand villages, besides several cities, which were destroyed by earthquakes. Its capital was named *Hecatompolis*, so called from the circumstance of its having a hundred gates.

The history of the ancient Parthians is involved in obscurity. All we know about them is, that they were first subject to the Medes, then to the Persians, and lastly to Alexander. After the death of the Macedonian conqueror, the province fell to Seleucus Nicator, and was held by him and his successors till the reign of Antiochus Theus, about two centuries and a half before Christ. At this time the Parthians revolted, and chose Arsaces as their king. Seleucus Callinicus, the successor of Antiochus Theus, attempted to reduce Arsaces; but the latter, having had time to strengthen himself, defeated his antagonist, and drove him out of the country. In a short time, however, Seleucus undertook another expedition against Arsaces, which proved still more unfortunate than the former; for being defeated in a great battle, he was taken prisoner, and died in captivity. The day upon which Arsaces gained this victory was ever afterwards observed amongst the Parthians as an extraordinary festival. Arsaces being thus established in his new kingdom, reduced Hyrcania and several other provinces; but he was at last killed in a battle against Ariarathes, king of Cappadocia. From this prince all the other kings of Parthia took the surname of *Arsaces*, as those of Egypt did that of *Ptolemy* from Ptolemy Soter.

Arsaces was succeeded by his son, who, having entered Media, made himself master of that country, whilst Antiochus the Great was engaged in war with Ptolemy Euergetes, king of Egypt. Antiochus, however, had no sooner found himself disengaged from that war, than he marched with all his forces against Arsaces, and at first drove him completely out of Media. But the latter soon returned with an army of a hundred thousand foot and twenty thousand horse, with which he put a stop to the progress of Antiochus; and a treaty was soon afterwards concluded, by which it was agreed that Arsaces should remain master of Parthia and Hyrcania, upon condition of assisting Antiochus in his wars with other nations.

Arsaces II. was succeeded by his son Priapatius, who reigned fifteen years, and left three sons; Phrahates, Mithridates, and Artabanus. Phrahates, the elder, succeeded to the throne, and reduced the Mardians, who had never been conquered by any but Alexander. His brother Mithridates, who was invested with the regal dignity, reduced the Bactrians, Medes, Persians, and Elymeans, and overran a great part of the East, penetrating beyond the boundaries of Alexander's conquests. Demetrius Nicator, who then reigned in Syria, endeavoured to recover these provinces; but his army was entirely destroyed, and he himself taken prisoner, in which state he remained till his death. After this victory Mithridates made himself master of Babylonia and Mesopotamia, so that all the provinces between the Euphrates and the Ganges were now subject to his sway.

Mithridates died in the thirty-seventh year of his reign, leaving the throne to his son Phrahates II. But the latter was scarcely settled in his kingdom when Antiochus Sidetes marched against him at the head of a numerous army, on the pretence of delivering his brother Demetrius, who was still detained in captivity. Phrahates was defeated in three pitched battles, in which he lost all the countries conquered by his father, and was reduced within the limits of the ancient Parthian kingdom. Antiochus, however, did not long enjoy his good fortune; for his numerous army being obliged to separate to such distances as prevented them, in case of any sudden attack, from reuniting, the inhabitants, whom they had cruelly oppressed, took advantage of this separation, and conspired with the Parthians to destroy them. And this they accordingly effected. The vast army of Antiochus, with the monarch himself, were slaughtered in one day, scarcely a single person having escaped to carry the news to Syria. Phrahates, elated with this success, proposed to invade Syria; but happening to quarrel with the Scythians, he was cut off with his whole army by that people.

Phrahates was succeeded by his uncle Artabanus. The new king, however, enjoyed his dignity for a very short time, being, a few days after his accession, killed in another battle with the Scythians. He was succeeded by Pacorus, who entered into an alliance with the Romans, and was, in his turn, succeeded by Phrahates III. This monarch took under his protection Tigranes, the son of Tigranes the Great, king of Armenia, gave the young prince his daughter in marriage, and invaded the kingdom with a design to place him on the throne of Armenia; but on the approach of Pompey he thought proper to retire, and soon afterwards solemnly renewed the treaty with the Romans. Phrahates was murdered by his children, Mithridates and Orodes; and soon afterwards the former was put to death by his brother, who thus became the sole master of the Parthian empire.

In his reign happened the memorable war with the Romans under Crassus. This was occasioned, not by any breach of treaty on the part of the Parthians, but by the shameful avarice of Crassus. At that time the Roman empire had been divided between Cæsar, Pompey, and Crassus; and in virtue of this partition, the eastern provinces had fallen to the lot of Crassus. No sooner was he invested with his new dignity, than he resolved to carry the war into Parthia, hoping to enrich himself with the spoils of a people who were then accounted wealthy. As the Parthians had religiously observed the treaty, some of the tribunes opposed him; but Crassus having, by the assistance of Pompey, carried every thing before him, left Rome in the year 55 before Christ, and pursued his march to Brundusium, where he immediately embarked his troops, and after a difficult passage reached the ports of Galatia. From Galatia Crassus hastened to Syria, and, in passing through Judea, plundered the temple of Jerusalem. He then marched to the river Euphrates, which he crossed on a bridge of boats, and, having entered the Parthian dominions, began hostilities. As the enemy had not expected an invasion, they were quite unprepared for resistance. Hence Crassus overran all Mesopotamia; and if he had taken advantage of the consternation into which the Parthians were at first thrown, he might also have reduced Babylonia. But instead of this he repassed the Euphrates early in the autumn, leaving only seven thousand foot and one thousand horse to garrison the places he had reduced; and having put his army into winter quarters in Syria, he gave himself wholly up to his favourite passion of amassing money.

Early in the ensuing spring, the Roman general drew out his forces, in order to pursue the war with vigour; but, during the winter, Orodes had collected a numerous army, and was well prepared to oppose him. Before he entered upon action, however, the Parthian monarch sent ambassadors to Crassus, to expostulate with him on his injustice in attacking an ally of the Roman empire; but Crassus, without attending to their representations, merely replied, that they should have his answer at Seleucia. Orodes, finding that a war was unavoidable, divided his army into two corps. At the head of one he marched towards Armenia, to oppose the king of that country, who had raised a considerable army to assist the Romans; and the other he sent into Mesopotamia, under the command of Surenas, an experienced general, by whose conduct all the cities which Crassus had reduced were quickly retaken. Some Roman soldiers who made their escape fled to the camp of Crassus, and filled his army with terror by the accounts they gave of the number, power, and strength, of the enemy. They stated that the Parthians were numerous, brave, and well disciplined; that it was impossible to overtake them when they fled, or escape from them when they pursued; that their defensive weapons were proof against the Roman darts, and their offensive weapons so sharp, that no buckler could resist them. Crassus looked upon all this as the effect of sheer cowardice. But the common soldiers, and even many of the officers, were so disheartened, that Cassius, who afterwards conspired against Cæsar, and most of the legionary tribunes, advised Crassus to suspend his march, and consider better of the enterprise before he proceeded farther. Crassus, however, obstinately persisted in his resolution, being encouraged by the arrival of Artabazus, king of Armenia, who brought with him six thousand horse, and promised to send ten thousand cuirassiers and thirty thousand infantry whenever he should stand in need of them. At the same time the latter advised the Roman general not to march his army through the plains of Mesopotamia, but to penetrate through the mountains of Armenia. He stated, that, as Armenia was a mountainous country, the enemy's cavalry, in which their main strength consisted, would there be entirely useless, and that the Roman army, in penetrating through this country, would be plentifully supplied with all manner of necessaries; whereas, if the general marched through Mesopotamia, he would be perpetually harassed by the Parthian horse, and frequently be obliged to lead his army through sandy deserts, where he would be distressed for want of water, and every kind of provisions. This salutary advice, however, was rejected, and Crassus entered Mesopotamia with an army amounting to forty thousand men.

The Romans had no sooner crossed the Euphrates than Cassius advised his general to advance to some of those towns in which the garrisons still remained, in order to halt and refresh his troops; or, if he disapproved of this, to march along the banks of the Euphrates to Seleucia, by which means he would prevent the Parthians from surrounding him, at the same time that he would be plentifully supplied with provisions from his ships. Crassus seemed to approve of this judicious advice; but he was dissuaded by Abgarus, king of Edessa, whom the Romans took for an ally, though he was in reality a traitor sent by Surenas to effect the destruction of the Roman army. Under the conduct of this faithless guide, the Romans entered a vast plain divided by many rivulets. Their march through this fine country proved easy; but the farther they advanced the worse the roads became, insomuch that they were at last obliged to climb up rocky mountains, which brought them to a dry and sandy plain, where they could find neither food to satisfy their hunger, nor water to quench their thirst. Abgarus then began to be suspected by the tribunes and other officers, who earnestly entreated Crassus not to follow him any longer, but to retreat towards the mountains; and at the same time an express arrived from Artabazus, informing the Roman general that Orodes had invaded his dominions with a great army, and that he was obliged to keep his troops at home to defend his own dominions. The same messenger advised Crassus, in his master's name, to avoid the barren plains, where his army would certainly perish with hunger and fatigue, and to approach Armenia, that they might unite their forces against the common enemy. But all was to no purpose. Crassus, instead of hearkening either to the advice of the king or to his own officers, first flew into a violent rage with the messengers of Artabazus, and then told his troops, that they were not to expect the delights of Campania in the most remote parts of the world.

They accordingly continued their march for several days across a desert, the very sight of which was sufficient to fill them with despair. They could not perceive, either near or at a distance, the least tree, plant, or brook, nay, not so much as a hill, or a single blade of grass; all around, nothing was to be seen but huge heaps of burning sand. The Romans had scarcely penetrated through this desert, when intelligence was brought them by their scouts, that a numerous army of Parthians was advancing in full march to attack them. In fact, Abgarus, on pretence of going out on parties, had often conferred with Surenas, and with him concerted measures for destroying the Roman army. Upon receiving this intelligence, which occasioned great confusion in the camp, the Romans being quite exhausted with their long and troublesome march, Crassus drew up his men in order of battle, at first following the advice of Cassius, who recommended extending the infantry as widely as possible, that they might occupy the more ground, and thus prevent the enemy from surrounding them. But Abgarus having assured the proconsul that the Parthian forces were not so numerous as had been represented, he changed this disposition, and, believing only the man who betrayed him, drew up his troops in a square, which faced every way, having on each side twelve cohorts in front; and near to each cohort he placed a troop of cavalry to support them, that they might charge with the greater security and boldness. Thus the whole army looked more like one phalanx than troops drawn up in manipules, with intervening spaces, according to the usual Roman formation. The general himself commanded the centre, his son had charge of the left wing, and to Cassius was committed the right.

In this order they advanced to the banks of a small river called the Balissus, the sight of which was very agreeable to the soldiers, who were much harassed with drought and excessive heat. When they came in sight of the enemy, they did not appear to be either so numerous or so terrible as had been represented. But this was a stratagem of Surenas, who had concealed his men in convenient places, ordering them to cover their arms, lest their brightness should betray them, and to start up at the first signal and attack the enemy on all sides. The stratagem had the desired effect. No sooner had Surenas given the signal, than the Parthians, rising as it were out of the ground, with dreadful yells advanced against the Romans, who were greatly surprised, not to say dismayed, at the sight; the more so as the Parthians, throwing off the covering of their arms, appeared in shining cuirasses, and helmets of burnished steel, finely mounted on horses covered all over with armour of the same metal. At their head appeared in a rich dress young Surenas, who immediately charged the enemy, endeavouring, by means of his pikemen, to break through the first rank of the Roman army; but finding it too close and impenetrable, the cohorts supporting each other, he fell back, and retired in seeming confusion. The Romans, however, were much surprised when they saw themselves suddenly surrounded on all sides, and galled with continual showers of arrows. Crassus ordered his light-armed foot and archers to advance and charge the enemy; but they were soon repulsed, and forced to cover themselves behind the heavy-armed infantry. Then the Parthian horse, advancing near the Romans, discharged upon them showers of arrows, every one of which did execution, owing to the close order in which the legionaries had been drawn up. Their arrows, too, were of an extraordinary weight, and discharged with such force that nothing was proof against them. The two wings advanced in good order to repulse them, but without effect. The Parthians shot their arrows with as great dexterity when their backs were turned as when they faced the enemy; so that the Romans, whether they kept their ground or pursued the flying enemy, were equally annoyed with their fatal missiles.

The Romans, as long as they had any hopes that the Parthians, after having spent their arrows, would either betake themselves to flight, or engage them hand to hand, stood their ground with great resolution and intrepidity. But when they observed that there were a great many camels in their rear loaded with arrows, and that those who emptied their quivers wheeled about to fill them anew, they began to lose courage, and to complain loudly of their general for suffering them thus to stand still, and serve only as a butt to the enemy's missiles, which, they perceived, would not be exhausted till they were all killed to a man. Upon this Crassus ordered his son to advance, at all hazards, and attack the enemy with thirteen hundred horse, five hundred archers, and eight cohorts. But the Parthians no sooner saw this choice body, the flower of the army, marching against them, than they wheeled about, and, according to their usual custom, betook themselves to flight. Young Crassus, crying out as loud as he could, "They fly before us," pushed on after them at full speed, not doubting that he should gain a complete victory. But when he was at a considerable distance from the main body of the Roman army, he perceived his mistake; for those who had before fled now faced about and charged him with incredible fury. Young Crassus ordered his troops to halt, hoping that the enemy, upon seeing their small number, would not be afraid to come to a close fight. But herein he was likewise disappointed; for the Parthians, contenting themselves to oppose his front with their heavy-armed horse, surrounded him on all sides, and, keeping at a distance, discharged incessant showers of arrows upon the unfortunate Romans. The Parthian army, in wheeling about, raised so thick a dust that the Romans could scarcely perceive one another, much less the enemy; nevertheless, they found themselves wounded with arrows, though they could not discover whence they came. In a short time the ground on which they stood was covered with dead bodies.

In this desperate condition, Crassus, observing a rising ground at a small distance, led the remains of his detachment thither, with a design to defend himself in the best manner he could, till succours should be sent to him by his father. The Parthians pursued him, and, having surrounded him in his new post, continued showering arrows upon his men, till most of them were either killed or disabled, without being able to make use of their arms, or to give the enemy proofs of their valour.

Young Crassus had with him two Greeks, who had settled in the city of Carrhæ. Touched with compassion at seeing so brave a man reduced to such straits, they pressed him to retire with them to the neighbouring city of Ischnes, which had declared for the Romans; but the young Roman rejected their proposal with indignation, telling them that he would rather die a thousand times than abandon so many valiant men, who sacrificed their lives for his sake. Having returned this answer to his Grecian friends, he embraced and dismissed them, giving them leave to retire and to shift for themselves in the best manner they could. As for himself, having now lost all hopes of being relieved, and seeing most of his men killed round him, he gave way to his grief; and, not being able to make use of his arm, which was shot through with a large barbed arrow, he presented his side to one of his attendants, and ordered him to put an end to his unhappy life. His example was followed by Censorius, a senator, by Megabacchus, a brave and experienced officer, and by most of the nobility who served under him. Five hundred common soldiers were taken prisoners, and the rest cut in pieces.

The Parthians, having thus cut off or taken the whole detachment commanded by young Crassus, marched without delay against his father, who, upon the first intelligence that the enemy were flying, closely pursued by his son, had taken heart, the more so because those who had remained to make head against him seemed to abate much of their ardour. Having encouraged his troops, therefore, he had retired to a small hill in his rear, to wait there till his son should return from the pursuit. Young Crassus had despatched frequent expresses to his father, to acquaint the general with his danger; but they had all fallen into the enemy's hands, and only the last, who had escaped with great difficulty, arrived safe, and informed him that his son was lost if he did not send him an immediate and powerful reinforcement. This news threw Crassus into the utmost consternation. A thousand affecting thoughts rose in his agitated mind, and disturbed his reason to such a degree that he scarcely knew what he was doing. However, the desire he had of saving his son, and the many brave Romans who were under his command, induced him immediately to march to their assistance; but he had not advanced far before he was met by the Parthians, who, with loud shouts and songs of victory, gave the unhappy father notice of his misfortune. They had cut off the head of young Crassus, and having fixed it on the point of a lance, were advancing full speed to fall on the father. As they drew near, Crassus was struck with the dismal and affecting spectacle; but though he suffered the deepest affliction, he had the presence of mind to stifle his grief, for fear of discouraging the army, and to cry out to the dismayed troops, "This misfortune is entirely mine; the loss of one man cannot affect the victory. Let us charge, let us fight like Romans; if you have any compassion for a father who has just now lost a son whose valour you admired, let it appear in your rage and resentment against these insulting barbarians." Thus Crassus strove to re-animate his troops; but his efforts proved unsuccessful. Their courage was quite sunk, as appeared from the faint and languishing shout which they raised, according to custom, before the action. When the signal was given, the Parthians, adhering to their usual mode of fighting, discharged on the legionaries clouds of arrows, which did such dreadful execution that many of the Romans, to avoid the arrows, which occasioned a long and painful death, threw themselves, like men in despair, on the enemy's heavy-armed horse, seeking from their spears a more speedy and easy kind of death. Thus the Parthians continued plying them incessantly with their arrows till night, when they left the field of battle, crying out that they would allow the father one night to lament the death of his son.

This was a melancholy night for the Romans. Crassus kept himself concealed from the soldiery, lying in the open air, upon the bare ground, with his head wrapped up in his paludamentum or military cloak, and, in that forlorn condition, exhibiting a great example of the instability of fortune, and a still greater of the pernicious effects of avarice, temerity, and ambition. Octavius and Cassius having approached him, endeavoured to raise him up and console him; but, seeing him quite sunk under the weight of his affliction, and deaf to all comfort, they summoned a council of war, composed of all the chief officers, in which it was unanimously resolved that they should decamp before break of day, and retire, without sound of trumpet, to the neighbouring city of Carrhæ, which was held by a Roman garrison. Agreeably to this resolution, they commenced their march as soon as the council broke up, which produced dreadful outcries amongst the sick and wounded, who, perceiving that they were to be abandoned to the mercy of the enemy, filled the camp with their complaints and lamentations. But their cries and tears, though very affecting, did not stop the march of the others, which, indeed, was very slow, in order to give the stragglers time to come up. There were only three hundred light horse, under the command of Ægnatius, who pursued their march without stopping, and arrived at Carrhæ about midnight. Ægnatius, calling to the centinels on the walls, desired them to acquaint Coponius, the governor of the place, that Crassus had fought a great battle with the Parthians; and, without saying a word more, or letting him know who he was, continued his march with all possible expedition to the bridge of Zeugma, which he passed, and by that means saved his troops. But he was much blamed for thus abandoning his general at so critical a moment.

The message which he sent to Coponius was of some temporary service to Crassus. For that commander, wisely conjecturing, from the manner in which the unknown person had given him the intelligence, that some misfortune had befallen Crassus, immediately ordered his garrison to stand to their arms; and having marched out, met Crassus, whom he conducted, with the remains of his army, into the city. The Parthians, though informed of his flight, did not offer to pursue him, observing therein the superstitious custom which obtained amongst them and the Persians, not to fight in the night; but when it was day, they entered the Roman camp, and having put all the wounded, to the number of about four thousand, to the sword, dispersed their cavalry all over the plain, in pursuit of the fugitives. One of the lieutenants of Crassus, named Vargunteius, having separated in the night from the main body of the army, with four cohorts, missed his way, and was overtaken by the enemy. At their approach he withdrew to a neighbouring hill, where he defended himself, with great valour, till all his men were killed, excepting twenty, who made their way through the enemy, sword in hand, and got safe to Carrhæ; but Vargunteius himself lost his life on the occasion.

In the mean time Surenas, not knowing whether Crassus and Cassius had retired to Carrhæ or chosen a different route, in order to be informed of the truth, and take his measures accordingly, despatched a messenger, who spoke the Roman language, to the city of Carrhæ, enjoining him to approach the walls, and acquaint Crassus himself, or Cassius, that the Parthian general was inclined to enter into a treaty with them, and demanded a conference. Both the proconsul and his quæstor Cassius spoke with the messenger from the walls; and, accepting the proposal with great joy, desired that the time and place for an interview might be immediately agreed upon. The messenger withdrew, promising to return quickly with an answer from Surenas. But that general no sooner understood that Crassus and Cassius were in Carrhæ, than he marched thither with his whole army, and, having invested the place, acquainted the Romans, that if they expected any favourable terms, they must deliver up to him Crassus and Cassius in chains. A council of the chief officers was summoned, in which it was thought expedient to retire from Carrhæ that very night, and to seek for another asylum. It was of the utmost importance that none of the inhabitants of Carrhæ should be made acquainted with their design till the moment of its execution; but Crassus, whose whole conduct evidently shows that he was labouring under some strange infatuation, imparted the whole matter in confidence to one Andromachus, choosing him for his guide, and relying injudiciously on the fidelity of a man whom he scarcely knew. Andromachus immediately informed Surenas of the design of the Romans; promising, at the same time, as the Parthians did not engage in the night, to manage matters so that they should not get out of his reach before daybreak. The traitor, pursuant to his promise, led them through many windings and turnings, till at last he brought them into deep marshy grounds, where the infantry were up to the knees in mire. Cassius, suspecting that their faithless guide had led them into those swamps with no good design, refused to follow him any longer; and returning to Carrhæ, took his route towards Syria, which he reached with five hundred horse. Octavius, with five thousand men under his command, being conducted by trusty guides, gained the mountains called by Plutarch and Appian *Sinnaci*, and there intrenched himself before daybreak.

As for Crassus, he was still entangled in the marshes, when Surenas, at sunrise, overtook him, and invested him with his cavalry. The proconsul had with him four cohorts and a small body of horse; and with these, in spite of all opposition, he gained the summit of another hill within twelve furlongs of Octavius, who seeing the danger that threatened his general, flew to his assistance with a small number of his men, and was soon followed by all the rest, who, charging the Parthians with great fury, disengaged Crassus, and obliged the enemy to abandon the hill. Upon the retreat of the enemy, they formed themselves into a hollow square, and, placing Crassus in the middle, made a kind of rampart round him with their bucklers, resolutely protesting, that none of the enemy's arrows should touch their general's body till they were all killed fighting in his defence. Surenas, unwilling to let his prey escape, surrounded the hill, as if he designed to make a new attack; but finding his Parthians very backward, and not doubting but the Romans, when night came on, would pursue their march, and get out of his reach, he had recourse again to artifice, and declared before some prisoners, whom he soon afterwards set at liberty, that he was inclined to treat with the proconsul of a peace, and that it was better to come to a reconciliation with Rome, than to sow the seeds of an eternal war, by shedding the blood of one of her generals.

Agreeably to this declaration, Surenas, as soon as the prisoners were released, advanced towards the hill where the Romans were posted, attended only by some of his officers, and, with his bow unbent, and open arms, invited Crassus to an interview. So sudden a change seemed very suspicious to the proconsul, who therefore declined the interview, till he was forced, by his own soldiers, to intrust his life with an enemy whose treachery they had all experienced. The legionaries flocked round him, and not only abused him in an outrageous manner, but even menaced him if he did not accept of the proposals made by the Parthian general. Seeing, therefore, that his troops were ready to mutiny, the proconsul began to advance, without arms or guards, towards the enemy, after having called the gods and all his officers to witness the violence his troops had offered him, and entreated all who were present, but especially Octavius and Petronius, two of the chief commanders, for the honour of Rome, their common mother, not to mention, after his death, the shameful behaviour of the Roman legionaries. Octavius and Petronius could not resolve to let him go alone, but attended him down the hill, as did likewise some legionaries, keeping at a distance. Crassus was met at the foot of the hill by two Greeks, who, dismounting from their horses, saluted him with great respect, and desired him, in the Greek tongue, to send some of his attendants, who might satisfy him that Surenas, and those who were with him, came without arms. Crassus then sent two brothers, of the Roscian family; but Surenas having caused them to be seized, advanced to the foot of the hill, mounted on a fine horse, and attended by the chief officers of his army. Crassus, who waited for the return of his two messengers, was surprised to see himself confronted by Surenas in person, when he least expected it. The Parthian general, perceiving, as he approached Crassus, that he was on foot, cried out, in a seeming surprise, "What do I see? a Roman general on foot, and we on horseback? Let a horse be brought for him immediately." "You need not be surprised," replied Crassus; "we are come only to an interview, each after the custom of his country." "Very well," answered Surenas, "there shall henceforth be a lasting peace between King Orodes and the people of Rome; but we must sign the articles of it on the banks of the Euphrates, for you Romans do not always remember your conventions." Crassus would have sent for a horse; but a very stately one, with a golden bit, and richly caparisoned, was brought to him by a Parthian, which Surenas presenting to him, "Accept this horse from my hands," said he, "which I give you in the name of my master King Orodes." He had scarcely uttered these words, when some of the king's officers, taking Crassus by the middle, set him upon the horse, which they began to whip with great violence before them, in order to make him quicken his pace. Octavius, offended at this insult, took the horse by the bridle; Petronius and the few Romans who were present seconded him, and all, flocking round Crassus, stopped his horse. The Parthians endeavoured to repulse them, and clear the way for the proconsul, upon which they began to jostle and push one another with great tumult and disorder. At last, Octavius, drawing his sword, killed one of the king's grooms; but, at the same time, another coming behind Octavius, with one blow laid him dead at his feet. Both parties fought with great resolution, the Parthians striving to carry off Crassus, and the Romans to rescue him out of their hands. In this scuffle most of the Romans who came to the conference were killed, and amongst the rest Crassus himself, but whether by a Roman or a Parthian is uncertain. Upon his death, the rest of the army either surrendered to the enemy, or, dispersing in the night, were pursued and put to the sword. The Romans lost in this campaign at least thirty thousand men; of whom twenty thousand were killed, and ten thousand taken prisoners.

When the battle of Carrhæ was fought, King Orodes was in Armenia, where he had made peace with Artabazus. Whilst the two kings were solemnizing their new alliance with expensive and public feasts, Styllaces or Syllaces, a Parthian officer, whom Surenas had sent with the news of his victory, and the head of Crassus as a proof of it, arrived in the capital of Armenia. The transports of joy which Orodes felt at this sight, and the tidings which accompanied it, are not to be expressed; and the lords of both kingdoms, who attended their sovereigns, raised loud and repeated shouts of joy. Syllaces was ordered to give a more particular and distinct account of that memorable action; and when he had done so, Orodes commanded molten gold to be poured into Crassus's mouth, thereby reproaching him with avarice, which had always been his predominant passion.

But Surenas did not long enjoy the pleasure of his victory; for Orodes, jealous of his power and authority amongst the Parthians, soon afterwards caused him to be put to death. Pacorus, the king's favourite son, was placed at the head of the army, and, agreeably to his father's directions, invaded Syria; but he was driven back with great loss by Cicero and by Cassius, the only general who had survived the defeat of Crassus. After this no mention is made of the Parthians till the time of the civil war between Cæsar and Pompey, when the latter sent ambassadors to solicit succour against his rivals. This Orodes was willing to grant, upon condition that Syria should be delivered up to him; but as Pompey would not consent to such a proposal, the succours were not only denied, but, after the battle of Pharsalia, Orodes put in irons Lucius Hirtius, whom Pompey had again sent to ask assistance, or at least to desire leave to shelter himself in the Parthian dominions.

Cæsar is said to have meditated a war against the Parthians, which, in all probability, would have proved fatal to them. His death delivered them from this danger. But, not long afterwards, the eastern provinces, being grievously oppressed by Marc Antony, rose in arms, and, having killed the tax-gatherers, invited the Parthians to join them in driving out the Romans. The latter readily accepted the invitation, and crossed the Euphrates with a powerful army under the command of Pacorus, and Labienus a Roman general of Pompey's party. At first they met with great success, and overran all Asia Minor, reducing the countries as far as the Hellespont and the Ægean Sea, and likewise subduing Phœnicia, Syria, and even Judea. They did not however long enjoy their new conquests. For, being elated with their victories, and despising the enemy, they engaged Ventidius, Antony's lieutenant, before Labienus had time to join them, and sustained a complete defeat. This so disheartened the army of Labienus, that they all abandoned him; and he himself, being thus obliged to wander from place to place in disguise, was at last taken and put to death at Cyprus. Ventidius, pursuing his advantage, gained several other victories; and at last entirely defeated the Parthian army under Pacorus, cutting almost the whole of them in pieces, and the prince himself amongst the rest. He did not, however, pursue this victory as he might have done, being afraid of giving umbrage to Antony, who had already become jealous of the great honour gained by his lieutenant. He therefore contented himself with reducing those places in Syria and Phœnicia which the Parthians had taken in the beginning of the war, until Antony arrived to take the command of the army upon himself.

Orodes was almost distracted with grief on receiving the dreadful news of the loss of his army, and the death of his favourite son. However, when time had restored the use of his faculties, he appointed Phrahates, the eldest but the most wicked of all his children, to succeed him in the kingdom, admitting him at the same time to a share of the sovereign authority. The consequence of this was, that Phrahates very soon attempted to poison his father with hemlock; but this, contrary to expectation, proving a cure for the dropsy, which an excess of grief had brought upon the king, the unnatural son caused him to be stifled in bed; and soon afterwards not only murdered all his own brothers, thirty in number, but also cut off the rest of the royal family, not sparing even his own eldest son, lest the discontented Parthians should place him, as he was already of age, upon the throne.

Many of the chief lords of Parthia, intimidated by the cruelty of Phrahates, retired into foreign countries. Amongst these was Monœses, a person of great distinction, as well as of skill and experience in war. This man, having fled to Antony, soon gained his confidence, and was by him easily prevailed upon to engage in a war against his countrymen. But Phrahates, justly dreading the consequences of the defection of such a person, sent a solemn embassy to invite him home upon such terms as he should think fit to accept; an offer which greatly provoked Antony, though he did not prevent him from returning, lest others should thereby be discouraged from coming over to him. He therefore dismissed him with great civility, sending ambassadors at the same time to Phrahates to treat of a peace. Thus he hoped to divert the attention of the Parthian monarch from making the necessary preparations for war, and that he should be able to fall upon the despot in the spring, when he was in no condition to offer resistance. But in this he was greatly disappointed; for on his arrival at the Euphrates, which he intended to pass, in order to enter the Parthian dominions on that side, he found all the defiles so well guarded, that he found it expedient to enter Media, with a design first to reduce that country, and then to penetrate into Parthia.

This plan had been suggested to him by Artabazus, king of Armenia, who in the end betrayed him; for instead of conducting the army the straight way from Zeugma on the Euphrates, to the Araxes, which separated Media from Armenia, and which was about five hundred miles distant from the place whence he first set out, Artabazus led him over the rocks and mountains, so that the army had marched above a thousand miles before they had reached the borders of Media, where they intended to begin the war. Thus they were not only greatly fatigued, but had not sufficient time, the year being far spent, to carry into effect the design which they had come to put in execution. However, as Antony was impatient to get back to Cleopatra, he left behind him most of the baggage of the army, and three hundred waggons loaded with battering rams and other military engines for sieges; appointing Statianus, one of his lieutenants, with a body of ten thousand men, to guard them, and to bring them, by slow marches, after the army. With the rest of the forces he marched more than three hundred miles, without allowing his men any respite till he arrived at Praaspa or Phrahata, the capital of Media, which he immediately invested. But the Parthians, well knowing that he could not make any progress without his military machines, passed by his army, in order to attack Statianus; which they did with so much success, that the body commanded by him were to a man cut off, and all their military engines taken, amongst which was a battering ram eighty feet in length.

Notwithstanding this disaster, Antony continued the siege of Praaspa; but was daily harassed by sallies of the garrison from within, and by the enemy's army without. At last, finding it impossible to make himself master of the city, he began to think of a retreat, when his provisions were almost exhausted. But as he had to march three hundred miles through the enemy's country, he thought proper first to send ambassadors to the Parthian monarch, acquainting him that the Roman people were willing to allow him a peace, provided he would restore the standards and prisoners taken at Carrhæ. Phrahates received the ambassadors sitting upon a golden throne; and, after having bitterly inveighed against the avarice and unbounded ambition of the Romans, told them that he would not part with the standards and the prisoners, but that if Antony would immediately raise the siege of Praaspa, he would suffer him to retire unmolested.

Antony, who was reduced to great straits, no sooner received this answer than he broke up the siege, and marched towards Armenia. However, Phrahates was not so good as his word; for the Romans were attacked on their march by the enemy no fewer than eighteen times, and were thrice in the utmost danger of being cut off. As a famine also raged in the Roman army, they began to desert to the enemy; and indeed Antony would probably have been left alone, had not the Parthians, in a very cruel as well as impolitic manner, murdered all those who fled to them, in sight of the rest. At last, after having lost thirty-two thousand men, and being reduced to such despair that he was with difficulty prevented from laying violent hands on himself, he reached the river Araxes; when his men, finding themselves out of the reach of the enemy, fell down on the ground, and kissed it with tears of joy.

Antony was no sooner gone than the kings of Media and Parthia quarrelled about the booty which they had taken; and, after various contests, Phrahates reduced all Media and Armenia. Elated with his conquests, he then oppressed his subjects in such a cruel and tyrannical manner that a civil war broke out, in which the competitors were alternately driven out and restored, until the middle of the first century, when one Vologeses, the son of Gortarzes, a former king, became peaceable possessor of the throne. He carried on some wars against the Romans, but with indifferent success, and at last gladly consented to a renewal of the ancient treaties with that powerful people.

From this time the Parthian history presents nothing remarkable until the reign of the Emperor Trajan, when the Parthian king, by name Cosdroes, infringed the treaty with Rome, by driving out the king of Armenia. Upon this Trajan, glad of any pretence to quarrel with the Parthians, immediately hastened into Armenia. His arrival there was so unexpected that he reduced almost the whole country without opposition, and took prisoner Parthamasiris, the king, who had been set up by the Parthians. After this he entered Mesopotamia, took the city of Nisibis, and reduced to a Roman province the whole of that wealthy country.

Early in the spring of the following year, Trajan, who had withdrawn to winter quarters in Syria, again took the field, but was warmly opposed by Cosdroes. The Roman emperor found him encamped on the banks of the Euphrates, with the design of disputing his passage, which in fact he did with so much vigour, that Trajan, after having several times attempted to ford the river, and been always repulsed, was obliged to cause boats to be built on the neighbouring mountains, which he privately conveyed thence on carriages to the water, and having in the night-time formed a bridge with them, his army passed the next day, though not without great loss and danger, the Parthians harassing his men all the time with incessant showers of arrows. Having gained the opposite bank, he advanced boldly into Assyria, the Parthians flying everywhere before him, and made himself master of Arbela; and thence he pursued his march, subduing, with incredible rapidity, countries where the Roman standard had never before been displayed. Babylonia voluntarily submitted to him, and Babylon itself was, after a vigorous resistance, taken by storm; so that he became master of all Chaldæa and Assyria, the two richest provinces of the Parthian empire. From Babylon he marched to Ctesiphon, the metropolis of the Parthian monarchy, which he besieged, and at last reduced. But whilst Trajan was thus making war in the heart of the enemy's country, Cosdroes, having recruited his army, marched into Mesopotamia, with the design of recovering that country, and cutting off all communication between the Roman army and Syria. On his arrival in that province the inhabitants flocked to him from all parts; and most of the cities, having driven out the garrisons left by Trajan, opened their gates to him. The emperor, however, detached Lucius and Maximus into Mesopotamia to keep in awe such cities as had not revolted, and to open a communication with Syria. Maximus was met by Cosdroes, and having ventured a battle, his army was entirely defeated, and himself killed. But Lucius being joined by Euricius and Clarius, two other commanders sent by Trajan with fresh supplies, gained considerable advantages over the enemy, and retook the cities of Nisibis and Seleucia, which had revolted.

Trajan, seeing himself thus possessed of all the best and most fruitful provinces of the Parthian empire, but at the same time being well aware that he could not, without vast expense, maintain his conquests, or keep in subjection so fierce and warlike a people, at so great a distance from Italy, resolved to place over them a king of his own choice, who should hold the crown of him and his successors, and acknowledge them as his lords and sovereigns. With this view he repaired to Ctesiphon, and having there assembled the chief men of the nation, he crowned one of the royal family, by name Parthanaspates, king of Parthia, obliging all those who were present to engage to pay him allegiance. Thus the Parthians were at last subdued, and their kingdom made tributary to Rome. But they did not long continue in this state of subjection. For no sooner had they heard of Trajan's death, which happened shortly afterwards, than they drove Parthanaspates from the throne, and, recalling Cosdroes, openly revolted against Rome. Hadrian, who was then commander-in-chief of all the forces in the East, and soon afterwards acknowledged as emperor by the army, did not wish, although he was at that time in Syria with a very numerous army, to engage in any new war with the Parthians; but contented himself with preserving the ancient limits of the empire, without any ambitious prospects of further conquests. He therefore abandoned those provinces beyond the Euphrates which Trajan had conquered, withdrew the Roman garrisons from Mesopotamia, and fixed the Euphrates as the boundary of the empire in those parts, posting his legions along the banks of that river.

Cosdroes died after a long reign, and was succeeded by his eldest son Vologeses. In the reign of the latter, the Alani, having broken into Media, which was then subject to the Parthians, committed great devastations, but were prevailed upon, with rich presents sent them by Vologeses, to abandon that kingdom, and return home. Upon their retreat, Vologeses, having no enemy to contend with at home, fell unexpectedly upon Armenia, surprised the legions, and, having cut them in pieces, entered Syria, defeated Attilius Cornelianus, governor of that province, and advanced without opposition to the neighbourhood of Antioch, putting everywhere the Romans, and those who favoured them, to the sword. The Emperor Verus, by the advice of his colleague Antoninus, surnamed the *Philosopher*, having left Rome, hastened into Syria; and having driven the Parthians out of that province, ordered Statius Priscus to invade Armenia, and Cassius to enter the Parthian territories, and carry the war into the enemy's country. Priscus made himself master of Artaxata, and in one campaign drove the Parthians out of Armenia. Cassius, on the other hand, having in several encounters defeated Vologeses, reduced in four years all those provinces which had formerly submitted to Trajan; took Seleucia, and burned and plundered the cities of Babylon and Ctesiphon, with the stately palaces of the Parthian monarchs; and struck terror into the most remote provinces of that empire.

However, Verus, who had never stirred from Antioch and Daphne during the whole time of the war, took upon him the lofty titles of *Parthicus* and *Armenicus*, as if he had acquired them in the midst of his pleasures and debaucheries. After the revolt and death of Cassius, Antoninus the Philosopher repaired to Syria to settle the affairs of that province. On his arrival he was met by ambassadors from Vologeses, who having recovered most of the provinces subdued by Cassius, and being unwilling either to part with them or to engage in a new war, solicited the emperor to confirm him in the possession of them; promising to hold them of him, and to acknowledge the sovereignty of Rome. To these terms Antoninus readily agreed, and a peace was accordingly concluded between the two empires.

Upon the death of Vologeses, the son of his brother Sanatruces, and grandson of Cosdroes, who bore the same name, was raised to the throne. He sided with Niger against the Emperor Severus, who, having settled matters at home, marched with all his forces against him; and advancing to the city of Ctesiphon, whither he had retired, laid close siege to that metropolis. Vologeses made a gallant defence, but the city was at length taken by assault. The king's treasures, with his wives and children, fell into the emperor's hands; but Vologeses himself had the good luck to make his escape. Severus, however, had no sooner crossed the Euphrates than Vologeses recovered all the provinces which he had reduced, except Mesopotamia. These expeditions cost the Romans a great amount of blood and treasure, without yielding any advantages in return. Vologeses was soon afterwards engaged in a war still more troublesome and destructive, with his brother Artabanus, who, encouraged by some of the discontented nobles, attempted to rob him of the crown, and to place it on his own head. Vologeses gained several victories over his rebellious subjects, but died before he could restore the empire to its former tranquillity.

Artabanus, who had a numerous army at his devotion, did not now meet with any opposition in seizing the vacant throne, although Tiridates had a better title to it, as being his elder brother. He had scarcely settled the affairs of his kingdom, when the Emperor Caracalla, desirous to signalize himself, as several of his predecessors had done, by some memorable exploit against the Parthians, sent a solemn embassy to their king, desiring his daughter in marriage. Artabanus, overjoyed at this proposal, received the ambassadors with all possible marks of honour, and readily complied with their request. Soon afterwards Caracalla sent a second embassy to acquaint the king that he was coming to solemnize the nuptials; upon which Artabanus went to meet him, attended with his principal nobility and his best troops, all unarmed. But this peaceable train no sooner approached the Roman army, than the soldiers, on a signal given them, fell upon the king's retinue, and made a most terrible slaughter of the unarmed multitude, Artabanus himself escaping with very great difficulty. Caracalla having by this abominable treachery gained great booty, and, as he thought, no less glory, wrote a long boastful letter to the senate, assuming the title of *Parthicus*, as he had before done that of *Germanicus*, for murdering, in a similar manner, some of the German nobility.

Artabanus having resolved to make the Romans pay dear for their inhuman and barbarous treachery, raised the most numerous army that had ever been known in Parthia, crossed the Euphrates, and entered Syria, which he ravaged with fire and sword. But Caracalla being murdered before this invasion, Macrinus, who had succeeded him, met the Parthians at the head of a mighty army, composed of many legions, and all the auxiliaries of the states of Asia. The two armies no sooner came in sight of each other than they engaged with the utmost fury. The battle lasted two days, both Romans and Parthians fighting so obstinately, that night only parted them, without any apparent advantage on either side. The field of battle was covered with dead bodies; about forty thousand, including both Romans and Parthians, having fallen in the conflict. Nevertheless Artabanus was heard to say that the battle was only begun, and that he would continue it till either the Parthians or Romans were cut in pieces to a man. But Macrinus, being apprised that the king came highly enraged against Caracalla, and dreading the consequences which would attend the destruction of his army, sent a herald to Artabanus, acquainting him with the death of Caracalla, and proposing an alliance between the two empires. The king, understanding that his great enemy was dead, readily embraced the proposal, upon condition that all the prisoners who had been so perfidiously taken by Caracalla should be immediately restored, and a large sum of money paid to defray the expenses of the war.

As Artabanus on this occasion had lost the flower of his army, Artaxerxes, a Persian of mean descent, but of great courage and experience in war, revolted against the Parthians, and, having prevailed on his countrymen to join him, attempted to recover the sovereign power, which, he said, they had been unjustly deprived of, first by the Macedonians, and afterwards by the Parthians their vassals. Upon the news of this revolt, Artabanus marched with the whole strength of his kingdom to suppress it; but being met by Artaxerxes at the head of an army no less powerful, a bloody battle ensued, which is said to have lasted three days. At length the Parthians, though they behaved with the utmost bravery, and fought like men in despair, were forced to yield to the Persians, who were commanded by a more experienced leader. Most of their troops were cut off in the flight; and the king himself having been taken prisoner, was soon afterwards put to death by order of Artaxerxes. In this fatal engagement, the Parthians having lost both their king and their army, were forced to submit to the conqueror, and become the vassals of a nation which had been subject to them for the space of four hundred and seventy-five years.

PARTI, Partie, *Party*, or *Parted*, in *Heraldry*, is applied to a shield or escutcheon, denoting that it is divided or marked out into partitions.

PARTICIPLE, in *Grammar*, an adjective formed of a verb, and so called because it participates partly of the properties of an adnoun and partly of those of a verb. See the article Grammar.

PARTICLE, in *Grammar*, a denomination for all those small words which connect or unite others, or express the modes or manners of words.

PARTISAN, in war, a person dexterous in commanding a party, and who, knowing the country well, is employed in getting intelligence, or surprising the enemy's convoys and posts. The word also means an officer sent out upon a party, with the command of a body of light troops, generally under the appellation of the partisan corps.

PARTNERSHIP, is a contract amongst two or more persons, to carry on a certain business, at their joint risk and expense, and to share the gain or loss arising from it.

PARTRIDGE, a species of bird. See Ornithology.

Partridge's *Island*, on the south coast of Van Diemen's Land, was so called by Entrecasteaux, the French navigator. Lat. 43. 23. S.

PARTY, in a military sense, a small number of men, horse or foot, sent upon any kind of duty, as into an enemy's country to pillage, to take prisoners, and to levy contributions. Parties are often sent out to examine the roads and ways, procure intelligence, forage, reconnoitre, or amuse the enemy upon a march; and they are also frequently sent upon the flanks of an army or regiment, to discover the enemy if near, and prevent surprise or ambuscade.

PARUPANADA, a town of Southern India, situated on the sea-coast of the province of Malabar. The small town of Vuypura was originally called the North Parupanada. It is pleasantly situated on the northern bank of a river, near the sea-coast, and which would be navigable for ships were it not for a large bar at its mouth. The other town of Parupanada contains 700 houses, mostly built of stone, and is well aired; and the surf, compared with that which breaks on the Madras shore, is trifling; so that, excepting in some places where rocky head-lands run into the sea, boats of any kind may without any danger land on the coast. From two to three thousand teak trees may be procured here annually. It is twenty-two miles south from Calicut. Long. 75. 55. E. Lat. 11. 2. N.

PARVICH, an island near Dalmatia, containing many

Roman antiquities, which evidently show that it was a Roman station. It seems to have been amongst the number of those islands which Pliny calls *Celadussæ*, supposed to be an inversion of δοσκελαδος, meaning *ill sounding* or *noisy*. Parvich is not of large extent, but is extremely fertile. Every product attains perfection there, particularly those which require a very shallow soil, such as wine, oil, mulberry trees, and fruit. The aspect of this island is also very pleasant at a distance, but that of the others adjacent shocks the eye by their high, rocky, and naked hills. The name of *Parvich* seems to have been given it because it is the first one observed on going out of the harbour of Sibenico; the Illyrian word *parvi* signifying *first*.

PASANGA, a small island in the Eastern Seas, near the western coast of Sumatra. Lat. 5. 10. S.

PASAY, a town of Sumatra, situated in a fine bay on the northern extremity of the island, abounding in cattle, provisions, and grain, and also in fine timber.

PASCAL, Blaise, one of the greatest geniuses and best writers that France has produced, was born at Clermont, in Auvergne, in the year 1623. His father, Stephen Pascal, born in 1588, and descended of an ancient family, was president of the court of aids in his province; and being a very learned man, and an able mathematician, he was a friend of Descartes. Having an extraordinary tenderness for this child, who was his only son, he quitted his office, and settled at Paris in 1631, that he might be at leisure to attend to his instruction; and young Pascal never had any master but his father. From his infancy he gave proofs of extraordinary capacity; for he desired to know the reason of every thing, and when good reasons were not given him, he would seek for better, refusing to yield his assent except upon such as appeared to him to be well grounded. It was feared that, with such a turn of mind, he might fall into free-thinking, or at least into heterodoxy; but this apprehension proved groundless.

What is told of his manner of learning the mathematics, as well as of the rapid progress which he made in that science, seems almost miraculous. His father, perceiving in him an extraordinary inclination to reasoning, was afraid lest the knowledge of the mathematics might prevent his acquiring the languages. He therefore kept him as much as he could from all notions of geometry, locked up all his books on that subject, and even refrained from speaking of it in his presence. He could not, however, prevent his son from musing upon geometrical propositions, and one day surprised him at work with some charcoal upon his chamber floor, and in the midst of figures. Having asked the boy what he was doing, he received for answer, I am searching for such a property, which was in fact that demonstrated in the thirty-second proposition of the first book of Euclid. His father then asked him how he came to think of this? It was, says Pascal, because I had found out such another thing; and so going backwards and using the names of *bar* and *round*, he came at length to the definitions and axioms which he had formed to himself. Does it not seem almost miraculous that a boy should work his way into the heart of a mathematical work, without ever having seen that or any other book upon the subject, or knowing any thing of the terms? Yet we are assured of the truth of this by Madame Perrier, and by several other writers, the credit of whose testimony cannot reasonably be questioned. Thenceforward he had full liberty to indulge his genius in mathematical pursuits. He understood Euclid's Elements as soon as he cast his eyes upon them; and this need not seem strange, for, as we have seen, he understood them before.

At sixteen years of age he wrote a treatise on Conic Sections, which was accounted by the learned a mighty effort of genius; and therefore it is not wonderful that Descartes, who had been a long time in Holland, should, upon reading it, have been inclined to believe that M. Pascal the father was the real author of the work. At nineteen he contrived an admirable mathematical machine, which was esteemed a wonderful thing, and would have done credit as an invention almost to any man conversant with science, far less to a mere youth. About this time his health became impaired, and he was in consequence obliged to suspend his labours; nor was he in a condition to resume them till nearly four years afterwards. About that period, having seen Torricelli's experiment respecting a vacuum and the weight of the air, he turned his thoughts towards that subject; and in a conference with M. Petit, intendant of fortifications, proposed to make farther researches. In pursuance of this idea, he undertook several new experiments. In particular, having provided a glass tube, forty-six feet in length, open at one end, and sealed hermetically at the other, he filled it with red wine, that he might distinguish the liquor from the tube. He then elevated the latter in this condition; and having placed it perpendicularly to the horizon, stopped up the bottom, and plunged it into a vessel full of water to the depth of a foot; after which he opened the extremity of the tube, and the wine descended till about thirty-two feet above the surface of the vessel, leaving a considerable vacuum at the upper extremity. He next inclined the tube, and remarked that the wine rose higher; and having inclined it till the top was within thirty-two feet of the ground, making the wine thus run out, he found that the water rose in it, so that it was partly filled with that fluid, and partly with wine. He made also a great many experiments with syphons, syringes, bellows, and all kinds of tubes, employing different liquors, such as quicksilver, water, wine, and oil; and having published an account of his experiments in 1647, he dispersed his work throughout all France, and also transmitted it to foreign countries. All these experiments, however, ascertained effects, without demonstrating the causes. Pascal knew that Torricelli conjectured that those phenomena which he had observed were occasioned by the weight of the air; and, in order to discover the truth of this theory, he made an experiment at the summit and foot of a mountain in Auvergne, called Le Puy-de-Dome, the result of which led him to conclude that air had weight. Of this experiment he also published an account, and sent copies of it to most of the learned men in Europe. He likewise renewed the experiment at the top of several high towers, such as those of Nôtre Dame at Paris, St Jacques de la Boucherie, and some others; and he always remarked the same difference in the weight of the air at different elevations. This fully convinced him of the weight of the atmosphere; and from this discovery he drew many useful and important inferences. He also composed a large treatise, in which he thoroughly explained this subject, and replied to all the objections which had been started against it. As he thought this work rather too prolix, and as he was fond of brevity and precision, he divided it into two small treatises, one of which he entitled a Dissertation on the Equilibrium of Liquors; and the other, an Essay on the Weight of the Atmosphere. These labours procured Pascal so much reputation, that the greatest mathematicians and philosophers of the age proposed various questions to him, and consulted him respecting such difficulties as they could not resolve.

Some years after, whilst tormented with a violent fit of the toothach, he discovered the solution of a problem proposed by Father Mersenne, which had baffled the penetration of all those who had attempted it. This problem was to determine the curve described in the air by the nail of a coach-wheel whilst the machine is in motion. Pascal offered a reward of forty pistoles to any one who should give a satisfactory answer to the question. As no one succeeded, however, he published his own at Paris; but as he now began to be disgusted with the sciences, he did not put his real name to it, and sent it abroad under that of A. d'Ettenville. This was the last work which he published in the mathematics; and his infirmities now increased so much that he was under the necessity of renouncing severe study, and of living so recluse that he scarcely admitted any person to see him.

After he had laboured thus successfully in mathematical and philosophical disquisitions, he forsook these studies and all human learning at once. He was not twenty-four years of age, when the perusal of some pious books had inspired him with this resolution; and he became as great a devotee as any age has produced. He now devoted himself entirely to a state of prayer and mortification. He had always in his thoughts the great maxim of renouncing all pleasures and all superfluity; and this he practised with rigour even in his illnesses, to which he was frequently subject, being of a very feeble habit of body. He had no violent affection for those he loved; and he even thought it sinful, since a man possesses a heart which belongs only to God. He found fault with some discourses of his sister, which she thought very innocent; and subjected himself to severe mortification and abstinence.

But though Pascal had thus abstracted himself from the world, yet he could not forbear paying some attention to what was passing in it; and he even interested himself deeply in the contest between the Jesuits and the Jansenists. The Jesuits, although they had popes and kings on their side, were yet decried by the people, who raked up afresh against them the assassination of Henry IV., and all the old stories which were likely to render them odious. Pascal went farther, and by his *Lettres Provinciales*, published in 1656, under the name of Louis de Montalte, made them the subject of the keenest irony and ridicule. These letters may justly be considered as a model of eloquence and humour. The best comedies of Molière have not more wit than the first part of them; and the sublimity of the latter part is equal to any thing in Bossuet. It is true, indeed, that the whole book was built upon a false foundation; for the extravagant notions of a few Spanish and Flemish Jesuits were artfully ascribed to the whole society. Many absurdities might likewise have been discovered amongst the Dominican and Franciscan casuists; but this would not have answered the purpose; for the whole raillery was to be levelled only at the Jesuits. The Provincial Letters were intended to prove that the Jesuits had formed a design to corrupt mankind; a design which no sect or society ever had or can have. Voltaire considers Pascal as the first of the French satirists; for Despreaux, says he, must be regarded as only the second. In another place, speaking of this work, he says, that examples of all the various species of eloquence are to be found in it. "Though it has been now written almost a hundred years, yet not a single word occurs in it savouring of that vicissitude to which living languages are so subject. Here then we are to fix the epoch when our language may be said to have assumed a settled form. The Bishop of Lucon, son of the celebrated Bussy, told me, that asking one day the Bishop of Meaux what work he would covet most to be the author of, supposing his own performances set aside, Bossuet replied, the Provincial Letters." These letters have been translated into all languages, and printed in every possible form. Some have said that there were decrees of formal condemnation against them; and, further, that Pascal himself, in his last illness, detested them, and repented of having been a Jansenist; but neither of these statements seems to rest upon any good authority. Father Daniel wrote an answer to the Provincial Letters, entitled the Dialogues of Cleander and Eudoxus. These celebrated Letters appear to have been the joint productions of Arnauld, Nicole, and Pascal. Nicole and Arnauld supplied the materials, which Pascal worked up into those finished productions that fixed the language in which they were written, and have been admired by every succeeding age, as well as by that in which they were first given to the world.

Pascal was only about the age of thirty when the Provincial Letters were published; yet he was extremely infirm, and soon afterwards his disorders increased so much that, conceiving his end to be fast approaching, he gave up all farther thoughts of literary composition. He resolved to spend the remainder of his days in retirement and religious meditation; and with this view he broke off all his former connections, changed his habitation, and spoke to no one, not even to his own domestics. He made his own bed, fetched his dinner from the kitchen, carried it to his apartment, and brought back the plates and dishes in the evening; so that he employed his servants only to cook for him, to go to town, and to do such other offices as he could not conveniently perform himself. In his chamber nothing was to be seen but two or three chairs, a table, a bed, and a few books. It had no kind of ornament whatever; he had neither a carpet on the floor nor curtains to his bed: But this did not prevent him from sometimes receiving visits; and when his friends appeared surprised to find him thus without furniture, he replied, that he had what was necessary, and that anything else would be a superfluity, unworthy of a wise man. He employed his time in prayer, and in reading the Holy Scriptures; and he wrote down such thoughts as this exercise inspired. Though his continual infirmities obliged him to use very delicate food, and his servants employed the utmost care in providing only what was excellent, he never relished what he ate, and seemed quite indifferent whether what they brought him was good or bad.

But although he had now abandoned intense study, and lived in the most temperate manner, his health continued to decline rapidly; and his disorders had so enfeebled his organs, that his reason became in some measure affected. He always imagined that he saw a deep abyss on his left side; and he never would sit down till a chair was so placed as to secure him from the fancied danger which he apprehended. His friends did everything in their power to banish this melancholy idea from his thoughts, and to cure him of his error, but without effect. Though he would become calm and composed for a little, yet the phantom would in a few moments return again and torment him with this painful delusion. The cause of his seeing this singular vision for the first time is said to have been the following. His physicians, alarmed on account of the exhausted state to which he was reduced, had advised him to substitute easy and agreeable exercise for the exhausting labours of the closet. One day, in the month of October 1654, having gone, according to custom, to take an airing on the Pont de Neuilly, in a coach and four, the two leading horses suddenly took fright opposite to a place where there was no parapet, and threw themselves violently into the Seine; but the traces having luckily given way, the carriage remained on the brink of the precipice. The shock which Pascal, in his languishing situation, must have received from this dreadful accident, may easily be imagined. It threw him into a fit, which continued for some time, and it was with great difficulty that he could be restored to his senses. After this period his brain became so disordered that he was continually haunted by the remembrance of his danger, especially when his infirmities prevented him from enjoying sleep. During the last years of his life, in which he exhibited a melancholy example of the humiliating changes which take place in this transitory world, and which, if properly considered, might teach mankind not to be too proud of those abilities, however splendid, which a moment may take from them, he attended all the stated prayers, visited every church in which relics were exposed, and had always a spiritual almanack, containing an account of all those places where particular acts of devotion were performed. On this occasion it has been said that religion renders great minds capable of little things, and little minds capable of great things.

In company Pascal was distinguished by his amiable behaviour, his easy, agreeable, and instructive conversation, and his great modesty. He possessed a natural kind of eloquence, which was in a manner irresistible; and no one ever had the happiness of meeting him, without being at once instructed and delighted. His divine humility showed itself in all things, attempered with a grace and simplicity which imparted to it an indescribable charm. Towards the close of his life he employed himself wholly in pious and moral reflections, writing down those which he judged worthy of being preserved. The first piece of paper that he could find was employed for this purpose; and he commonly put down only a few words of each sentence, as he wrote them merely for his own use. The bits of paper upon which he had written these thoughts were found after his death filed upon different pieces of string, without any order or connection; but being copied exactly as they were written, they were afterwards arranged and published. He died at Paris on the 19th of August 1662, aged thirty-nine years.

The works of Pascal were collected in five volumes octavo, and published at the Hague by De Tune, and at Paris by Nyon, in 1779. This edition of Pascal's works may be considered as the first published; at least the greater part of them were not before collected into one body, and some of them had still remained in manuscript. For this collection the public were indebted to the Abbé Bossu, and Pascal deserved to have such an editor. See remarks on his philosophical character in the *First Dissertation*, prefixed to this work.

PASCO, a province of Peru, in the department of Junin, and celebrated for its mines of silver and gold, particularly the former. This district is situated at a prodigious elevation, some parts of it being more than 14,000 feet above the level of the sea, and is consequently much colder than its latitude would indicate, which is only about eleven degrees south of the equator. The following notice of Pasco is from an article in the Journal of the Geographical Society, giving an account of the recent travels of Dr Poeppig in this country: "He then entered the plain of Bonbon, in which the rich silver mines of Pasco are situated, and which extends upwards of six leagues in width from east to west. The greatest part of the waters collected on this plain run to the lake Lauricocha, the source of the Amazon. The Cerro de Pasco, in whose neighbourhood the richer mines are situated, is an irregularly built place, with about 7000 inhabitants (Lieutenant Smyth, in 1834, says from 12,000 to 16,000 inhabitants), and stated at 14,280 feet above the sea. From the Cerro de Pasco the author gradually descended in a northerly direction, by the eastern declivity of the Andes, to a valley traversed by the upper branch of the Huallaga, called Huanuco. At Coxamarquilla, a village more than three leagues from the Cerro, the ground had already so much lowered, that he found there plantations of vegetables. Trees made their appearance lower down; and at San Rafael he saw the first fields of wheat, which ascends in the valleys of the Andes to an elevation of 9000 feet. Before reaching the town of Huanuco, the level part of the valley was covered with sugar-cane plantations, and even the less steep declivities of the mountains on both sides were cultivated. Dr Poeppig followed the course of the Huanuco or Huallaga, from its source to its mouth. This river, which traverses more than five degrees of latitude, rises in the plain of Bonbon, in the Laguna de Chiquiacoba, not far from the Cerro, at an elevation of 13,200 feet above the sea. This alpine lake is only separated by a low ridge of hills from the Laguna de Quiluacocha, from which the Rio Mantaro, one of the principal branches of the Apurimac, issues under the name of Rio de San Juan. The Rio Huanuco runs first north as far as the town of Huanuco, then east about fifty miles with great violence through a rather narrow vale, and then it turns suddenly to the north-north-west and north, which course it pursues to its junction with the Amazon." Before the revolution the mines of Pasco yielded annually 131,000 lbs. troy of silver. During that convulsion the costly machinery was destroyed, and the water was allowed to take full possession of the mines. Both loyalists and patriots repeatedly plundered the stores, and for a long time operations were nearly suspended. This province is noted only for its mines. It is divided into three districts, each of which has its church and priest; but, in spite of the efforts of the latter, the miners belonging to the different districts live in a state of almost perpetual hostility with each other. When Lieutenant Smyth visited the mines of Pasco in 1834, the working of them had been resumed with some spirit; but the steam-engines which had been erected by an English company some years before were found either destroyed, or so much injured as to be unfit for use. These mines were discovered in the year 1630, by Huari Capac, an Indian.

PASIGRAPHY (from πας, *omnis*, and γραφω, *scribo*), the art of writing on any subject whatsoever, so as to be universally understood by all nations of the earth. The idea of establishing such a language is deemed by many extremely fanciful and absurd, whilst the practicability of it is as strenuously contended for by others. Hints respecting such a system of writing as might be understood by all mankind are to be met with in the writings of many eminent philosophers; but the attempt has signally failed, even in the hands of a Leibnitz, a Kircher, a Becher, and a Wilkins. Kant is clearly of opinion, however, that such a pasigraphy falls within the limits of possibility; nay, he even prognosticates that it will certainly be established at some future period.

PASIHAN, one of the smaller Philippine Islands, near the west coast of Leyta. Long. 124. 12. E. Lat. 10. 35. N.

PASIPHAE, in fabulous history, a daughter of the Sun by Perseis, and who married Minos, king of Crete. She disgraced herself by an unnatural passion for a bull, which we are told she was enabled to gratify by a contrivance of the artist Dædalus. This celebrated bull had been given to Minos by Neptune to be offered on his altars. But as the monarch refused to sacrifice the animal on account of his beauty, the god revenged his disobedience by inspiring Pasiphaë with an unnatural love for him. This fable, which is universally believed by the poets, is discarded by some writers, who suppose that the infidelity of Pasiphaë to her husband was betrayed in her affection for an officer of the name of Taurus, and that Dædalus, by permitting his house to be the place of assignation between the two lovers, was looked upon as accessory to the gratification of Pasiphaë's passion. From this amour with Taurus, as is farther remarked, the queen became mother of twins; and the name of *Minotaurus* arose from the resemblance of the children to the husband and the lover of Pasiphaë. Minos had by Pasiphaë four sons, Castreus, Deucalion, Glaucus, and Androgeus; and three daughters, Hecate, Ariadne, and Phædra.

PASQUIN, a mutilated statue at Rome, in a corner of the palace of the Ursini. It takes its name from a cobbler of that city, called *Pasquin*, famous for his sneers and gibes, and who diverted himself by cracking his jokes upon all who passed through that street. After the death of the cobbler, as some persons were digging up the pavement before his door, they found in the earth the statue of an ancient gladiator, well cut, but maimed and half spoiled; and having set up this in the place where it was found, they by common consent named it *Pasquin*. Since that time all satires are attributed to the figure in question, and are either put into its mouth, or pasted upon it, as if they were written by Pasquin himself. They are addressed by Pasquin to Marforio, another statue at Rome. When Marforio is attacked, Pasquin comes to his assistance; and when Pasquin is attacked, Marforio defends him in his turn; in other words, the people make the statues say just what they please.

PASQUINADE, a satirical libel fastened on the statue of Pasquin. Such productions are commonly short, witty, and pointed; and hence the term has been applied to all lampoons of this description.

PASS, or Passade, in fencing, an advance or leap forward upon the enemy. Of these there are several kinds, as passes within, above, beneath, to the right, to the left, and passes under the line. The measure of the pass is when the swords are so near that they may touch one another. See Fencing.

PASSADE, in the manège, is a turn or course of a horse backwards or forwards on the same spot of ground. Hence there are several sorts of passades, according to the different ways of turning, in order to part or return upon the same tread, which is called *closing the passade;* as the passade of one time, the passade of five times, and the raised or high passades.

PASSAGE Island, a small island amongst the Philippines, about twenty miles east from the island of Leyta. Long. 125. 27. E. Lat. 10. 44. N.

Passage *Isle*, a small island on the northern coast of Sumatra, which here forms a deep bay, where there are several Malay ports. Long. 97. 55. E. Lat. 2. 31. N.

PASSAGES, a seaport town of the province of Guipuscoa, in Spain. It stands on both banks of the river Oyarzun, near to the place where it falls into the Bay of Biscay, and having its entrance defended by the castle of St Isabel. The harbour was formerly adapted to admit the largest ships, but it is now so injured by the sand accumulated at its mouth, as to be accessible only to vessels of light draught of water. It still has a naval arsenal and hospital, and capacious storehouses, though but little use is made of them. It has two churches, a chapel, and an hospital, with 520 houses, and 2400 inhabitants, many of whom find employment in the fisheries. Long. 2. 0. 5. W. Lat. 43. 20. 30. N.

PASSAMAN, a small province of Sumatra, being one of the most northerly, and situated immediately under the equinoctial line. It was formerly subject to the dominion of Menancabow, but is now subject to the Achinese. It is divided into a number of petty kingdoms, each of which is governed by a rajah, and was formerly a place of considerable trade. Besides exporting large quantities of pepper, it received much fine gold from the mountains that are situated about three days' journey inland.

PASSANT, in *Heraldry*, a term applied to a lion or other animal in a shield, which appears to walk leisurely. For most beasts, except lions, the term *trippant* is frequently used instead of that of *passant.*

PASSAROUANG, a small town and fort on the northern shore of the island of Java. It is the capital of a large principality, and is intersected by a large river, over which there is a wooden bridge. It is pleasantly situated, has a healthy climate, and its native population is numerous. The surrounding country is fertile, and produces abundant crops of rice and maize. The roads are good; posts have been established along the coast; and it appears to be in all respects a busy and well-regulated settlement. It is situated in longitude 113. 10. east, and latitude 7. 3. south.

PASSAU, a city of the kingdom of Bavaria, in the circle of the Lower Danube, being the capital of the circle, as well as that of the bailiwick, of the same name. It is situated on a peninsula, formed by the junction of the river Inn with the Danube. It is strongly fortified, and farther defended by a citadel and the castle of Oberhaus. There are handsome bridges over both the Danube and the Inn. It is the see of a bishop, who has a palace and a cathedral, and it contains 822 houses, with 10,350 inhabitants. Notwithstanding its very advantageous situation on two navigable rivers, it enjoys very little trade, and has only some small manufactures. Long. 12. 54. E. Lat. 48. 35. N.

PASSION is a word of which, as Dr Reid observes, the meaning is not precisely ascertained either in common discourse or in the writings of philosophers. In its original import, it denotes every *feeling* of the mind occasioned by an extrinsic cause; but it is generally used to signify some *agitation* of mind, opposed to that state of tranquillity in which a man is most master of himself. That it was thus used by the Greeks and Romans, is evident from Cicero's rendering παθος, the word by which the philosophers of Greece expressed it, by *perturbatio* in Latin. In this sense of the word, passion cannot be itself a distinct and independent principle of action, but only an occasional degree of vehemence given to those dispositions, desires, and affections, which are at all times present to the mind of man; and that this is its proper sense, we require no other proof than that passion has always been conceived to bear an analogy to a storm at sea or to a tempest in the air. See Moral Philosophy.

Passion-Week, the week immediately preceding the festival of Easter, and so called because in that week happened our Saviour's passion and death. The Thursday of this week is called Maunday Thursday; the Friday, Good Friday; and the Saturday, the Great Sabbath.

PASSIR, a town and district of Borneo, pleasantly situated on a river of the same name, about fifty miles from its mouth, near the bottom of a large bay, on the eastern side of the island. The river is joined by five other tributary streams, and is very rapid near the town, above which the tide ascends, rising to the height of several feet. The town consists of three hundred wooden houses, situated on the northern side of the river, most of them inhabited by Buggess merchants. This was formerly a place of considerable trade. In the year 1772 the East India Company attempted to establish a factory here for the sale of opium, piece-goods, &c.; but the plan was frustrated by a commotion amongst the natives, at which the English commander took an alarm, and quitted the country. Passir has since this period been seldom visited by Europeans; more especially since several vessels have been cut off by the numerous pirates who frequent the coast and the neighbouring islands. The Chinese who have settled here are remarkably industrious, and are in possession of the principal trade. The surrounding country is fertile, and yields in great abundance rice, besides benzoin, aloes, pepper, cassia, and long nutmegs; also various kinds of fruit, excellent mastic and other gums, particularly dragon's blood; honey, gold dust, and camphor. The imports are nearly similar to those of the other Malay ports, namely, opium, fire-arms, gunpowder, lead, iron, and steel, cutlery, swords, cloths, chintzes, looking-glasses, &c. The inhabitants do not bear a good character. They are fraudulent and treacherous, and have cut off many ships in the most treacherous manner. They are also unjust in their weights and measures, and are expert in the practice of various other frauds. The country is flat and unhealthy, being covered with thick woods, and annually overflowed. The exhalations from this moisture, and the thick fogs, are extremely insalubrious. The thick fogs turn to rain, and are accompanied by chilling winds. The great numbers of frogs and vermin which are generated by the heat, and afterwards destroyed, occasion an intolerable stench, and add to the unhealthiness of the place. Long. of the town 116. 10. E. Lat. 1. 57. N.

PASSIVE, in general, denotes something that suffers the action of another, which is called an agent or active power. In grammar, the verb or word which expresses this passion is termed a *passive verb*, and, in the learned languages, has a peculiar termination; as, *amor*, *doceor*, *legor*, in Latin, that is, an *r* is added to the actives, *amo*, *doceo*, *lego;* and, in

sive
O ience

P over.

Passover.

the Greek, the inflection is made by changing ω into ομαι, as τυπτω, τυπτομαι, and πειθω, πειθομαι. But in the modern languages the passive inflection is effected by means of auxiliary verbs, joined to the participle of the past tense; as, *I am praised*, in Latin *laudor*, and in Greek ἐπαινεομαι; or, *I am loved*, in Latin *amor*, and in Greek φιλεομαι. Thus it appears that the auxiliary verb *am* serves to form the passives of English verbs: and the same thing holds of the French, as *Je suis loué*, I am praised; *j'ai été loué*, I have been praised, and so forth. See the article GRAMMAR.

PASSIVE Obedience, a political doctrine, very obnoxious to the friends of freedom. Some nonjurors, imagining that monarchy is the only lawful form of government, and that hereditary monarchy is the only lawful species of that government, have coupled with passive obedience the ridiculous notion of a divine, hereditary, indefeasible right in certain families to govern with despotic sway all other families of the same nation. The absurdity of this notion scarcely needs refutation; but it may not be improper to observe, that it has nothing to do with passive obedience.

This, as taught by the ablest reasoners, who think that they are supported by the Holy Scripture, is as much a duty under republican as under monarchical governments; and it means no more than that private individuals are bound, both by moral and religious ties, not to resist the supreme power, wheresoever it may be placed, in any nation. The supreme power can only be the legislature; and no man or body of men, who have not the power of enacting and abrogating laws, can, upon this principle, claim passive obedience from any subject. Whether the principle be well or ill founded, the absurdity which commonly attaches to the phrase *passive obedience* originates from the mistaken loyalty of the adherents of the house of Stuart, who, to aggravate the illegality of the Revolution, were accustomed to represent James II. as supreme over both houses of parliament, and of course also over all law. That such reveries were foolish, we need no other evidence than the statute-book, which shows, that in the office of legislation, the King, Lords, and Commons, are co-ordinate; and that when any one of these powers shall take upon itself to counteract the other two, even the duty of passive obedience will oblige the subject to support the legislature. That resistance to the legislature can only be lawful to oppose insupportable tyranny, has been shown by Mr Hume with great cogency of argument. That it can never be lawful on any occasion, Bishop Berkeley has endeavoured to prove by a chain of reasoning, which must, at least, be allowed to display considerable ingenuity and force. On this subject we refer our readers to Hume's Essays, Berkeley's tract on Passive Obedience and Non-resistance, and Locke's Essay on Government.

PASSOVER, a solemn festival of the Jews, instituted in commemoration of their exod from Egypt, because, the night before their departure, the destroying angel, who put to death all the first-born of the Egyptians, passed over the houses of the Hebrews without entering therein, as they were marked with the blood of the lamb which had been killed the evening before, and which, for this reason, was called the *paschal lamb*. This feast was called *pascha* by the Greeks and Romans, not, we presume, from πασχω, *I suffer*, as Chrysostom, Irenæus, and Tertullian suppose, but from the Hebrew word PESAH, signifying *passage*. What God ordained concerning the passover of the Jews is contained in Exodus (c. xii.). The month of the departure from Egypt was looked upon, from this time, as the first month of the sacred or ecclesiastical year; and on the fourteenth day of this month, between the two vespers, that is, between the sun's decline and his setting, or rather, according to our manner of reckoning, between two o'clock in the afternoon and six o'clock in the evening, at the equinox, they were required to kill the paschal lamb, and to abstain from leavened bread. The day following, being the fifteenth, reckoning from six o'clock of the foregoing evening, which concluded the fourteenth day, was the grand feast of the passover, which continued seven days. But it was only the first and the seventh day that were solemn. The lamb killed was to be without any defect, a male, and yeaned that year. If no lamb could be found, they might take a kid. They killed a lamb or a kid in every family; and if the number of those who lived in the house was not sufficient to eat a lamb, two houses might join together. With the blood of the paschal lamb they sprinkled the door-posts and lintels of every house, that the destroying angel, at the sight of the blood, might pass over them, and thus spare the Hebrew children. They were required to eat the lamb the same night that followed the sacrifice. They ate it roasted, with unleavened bread, and a salad of wild lettuce; the Hebrew says literally, with bitter things, as mustard, or any thing of this nature, to give it a relish. It was forbidden to eat any part of it raw, or boiled in water, nor were they to break a bone of the victim;[1] and if any thing remained until the day following, it was thrown into the fire. They who ate of it were to be in the posture of travellers, having their loins girt, their shoes on their feet, their staves in their hands, and eating in a hurry. But this last part of the ceremony was little observed, at least it was of no obligation, excepting only on that night when they went forth out of Egypt. During the whole eight days of the passover no leavened bread was to be used; and whoever should eat any, was threatened with being cut off from his people.

The Jews observed the first and last day of the feast, yet so as that it was allowed to dress victuals, which was forbidden on the Sabbath-day. The obligation of keeping the passover was so strict, that whoever neglected to do it was condemned to death.[2] But those who had any lawful impediment, as a journey, sickness, or any uncleanness, voluntary or involuntary, as, for example, those who had been present at a funeral, or by any other accident had been defiled, were to defer the celebration of the passover till the second month of the ecclesiastical year, or till the fourteenth day of the month Jair, which answers to April and May. It was thus that the Lord ordered Moses, upon the occasion of an inquiry by some Israelites, who had been obliged to pay the last offices to some of their relations, and who being thus polluted, were not capable of partaking of the paschal sacrifice.[3] The modern Jews observe in general the same ceremonies which were practised by their ancestors in the celebration of the passover. Upon the fourteenth of Nisan, the first-born fast in memory of God's smiting the first-born of the Egyptians; but the morning prayers are the same with those which are said on other festivals. They take the roll of the Pentateuch out of the chest, and read as far as the end of the twelfth chapter of Exodus, and also what is contained in the eighteenth chapter of Numbers, relating to the passover. The matron of the family then spreads a table, and sets on it two unleavened cakes, and two pieces of the lamb, a shoulder boiled and another roasted, to put them in mind that God had delivered them with a stretched-out arm. To this they add some small fishes, because of the leviathan; a hard egg, because of the ziz; some meal, because of the behemoth, these three animals being appointed for the feast of the elect in the other life; and pease and nuts for the children, to provoke their curiosity to inquire into the reason of the ceremony. They likewise use a kind of mustard, which has the appearance of mortar, to represent their making bricks in Egypt. The father of the family sits down

Passport.

along with his children and slaves, because upon this day all are free. Being seated, he takes bitter herbs, and dips them in the mustard, then eats, and distributes to the rest. All then partake of the lamb, the history and institution of which is at the same time recited by the master of the family. The whole repast is attended with hymns and prayers. They pray for the prince under whose dominion they live, according to the advice of Jeremiah (xxix. 7), "Seek the peace of the city whither I have caused you to be carried away captives, and pray unto the Lord for it; for in the peace thereof shall ye have peace." The same things are put in practice during the two following days; and the festival is concluded by the ceremony called *habdala*, or distinction. This ceremony is performed at the close of the Sabbath-day, at which time the master of the house usually pronounces certain benedictions, accompanied with certain formalities, requesting that everything may succeed well the week following. After going out of the synagogue, they eat leavened bread for the last time.[1] Whilst the temple remained, they brought thither their lambs, and there sacrificed them, offering the blood to the priest, who poured it out at the foot of the altar. The passover was typically predictive of Christ, who is the Christian passover.[2] As the destroying angel passed over the houses marked with the blood of the paschal lamb, so the wrath of God passes over those whose souls have been sprinkled with the blood of Christ. The paschal lamb was killed before Israel was delivered; so it was necessary that Christ should suffer before we could be redeemed. It was killed before Moses's law or Aaron's sacrifices were enjoined, to show that deliverance comes to mankind by none of them, but only by the true passover, that Lamb of God slain from the foundation of the world.[3] It was killed the first month of the year, which prefigured that Christ should suffer death in this month.[4] It was killed in the evening;[5] and so Christ suffered in the last days, and at this period of the day.[6] At evening also the sun sets, which shows that it was the Son of righteousness who was to suffer and die, and that at his passion universal darkness should overshadow the earth.[7] The passover was roasted with fire, to denote the sharp and dreadful pains which Christ should suffer, not only from men, but also from God. It was to be eaten with bitter herbs, not only to put them in remembrance of their bitter bondage in Egypt, but also to typify our mortification to sin, and readiness to undergo afflictions for Christ.[8] Many persons erroneously imagine that the passover was instituted in memory of the Israelites having passed the Red Sea; although it is certain the feast was held, and received its name, before the Israelites left Egypt, and consequently several days before they passed the Red Sea. Besides the passover celebrated on the fourteenth of the first month, there was a second passover, held on the fourteenth of the second month after the equinox, instituted by God in favour of travellers and sick persons, who could not attend at the first, nor be present at Jerusalem on the day. The Greeks, and even some of the Catholic doctors, take occasion, from the thirteenth, eighteenth, and nineteenth chapters of St John, to conclude, that Jesus anticipated the day marked for the passover in the law; but the authority of three evangelists seems to establish the contrary.

PASSPORT, or PASS, a license or writing obtained from a prince or governor, granting permission and a safe conduct to pass through his territories without molestation. It is also a permission granted by any state to navigate in some particular sea, without hindrance or molestation.

PASSUMAH, a district situated on the west coast of Sumatra. It is an extensive and populous country, governed by four independent chiefs, who acknowledge the sovereignty of the sultan of Palembang.

PASTEBOARD, a kind of thick paper, formed of several single sheets pasted one upon another. The chief use of pasteboard is for binding books, making letter-cases, and other articles.

PASTERN *of a* HORSE, in the manège, is the distance between the joint next the foot and the coronet of the hoof. This part should be short, especially in middle sized-horses, because long pasterns are weak, and cannot so well endure travelling.

PASTIL, or PASTEL, amongst painters, a kind of paste which is made of different colours, ground up with gum-water, in order to form crayons.

PASTIL, in *Pharmacy*, is a dry composition of sweet-smelling resins, aromatic woods, and the like, which is sometimes burnt to clear and scent the air of a chamber.

PASTIME, any sport, amusement, or diversion. Pastimes of some kind seem to be absolutely necessary, and to none more than to the man of study; for the most vigorous mind cannot bear to be always kept on the stretch. The sports, amusements, pleasures, and recreations, of our ancestors, as described by Fitz-Stephen,[9] added strength and agility to the wheels of state mechanism, whilst they had a direct tendency towards utility. Most of these ancient recreations are resolvable into the public defence of the state against the attacks of a foreign enemy. The play at ball, derived from the Romans, was first introduced by this author as the common exercise of every school-boy. The performance was in a field, whither the most substantial and considerable citizens resorted to give encouragement and countenance to this feat of agility. The intention of the amusement at this period of time was to render the juvenile race active, nimble, and vigorous; qualities which were requisite whenever their assistance should be wanted for the protection of their country. The next species of pastime indeed does not appear to have had this tendency; but it was only, as it should seem, an annual custom. This was cock-fighting. The author informs us, that in the afternoon of Shrove-Tuesday, upon which day this custom prevailed, they concluded it by throwing the ball; which seems to insinuate that cock-fighting was merely in conformity to ancient usage, and limited only to part of the day, in order to make way for a more laudable performance. We may reasonably suppose, although our author is entirely silent upon this head, that whilst cock-fighting was going on, cock-throwing was the sport of the lowest class of people, who could not afford the expense of the former. Another species of manly exercise was truly martial, and intended to qualify the adventurers for military discipline. "Every Friday in Lent," says Fitz-Stephen, "a company of young men comes into the field on horseback, attended and conducted by the best horsemen; then march forth the sons of the citizens, and other young men, with disarmed lances and shields, and there practise feats of war. Many courtiers likewise, when the king is near the spot, and attendants upon noblemen, do repair to these exercises; and while the hope of victory does inflame their minds, they show by good proof how serviceable they would be in martial affairs." This is evidently of Roman descent, and immediately brings to our recollection the *ludus Trojæ*, supposed to be the invention, as it was the common exercise, of Ascanius. The common people, in this age of masculine manners, made every amusement where strength was exerted the subject-matter of instruction and improvement. They were taught to exert their bodily strength in the maintenance of their country's rights; and their minds were also improved by such exertion, being formed to every manly and generous principle.

[9] Otherwise called William Stephanides, a monk of Canterbury, who lived in the reigns of Stephen and Richard I. He wrote a Latin treatise, in which he gives an account of the several pastimes which were countenanced in his time. Bale, in his writings, draws a pleasing portrait of this person; and he is likewise sketched with much commendation by Leland. "The time which other people usually misemployed in an idle and frivolous manner," says Bale, "he consecrated to inquiries which tended to increase the fame and dignity of his country; in doing which, he was not unworthy of being compared to Plato, for, like him, he made the study of men and heaven his constant exercise."

In the intervals of industry and labour, commonly called the holidays, indolence and inactivity, which at this day prevail, were found only in those whose lives were distempered with age or infirmity. The view which Fitz-Stephen gives us of the Easter holidays is animated. "In Easter holydays they fight battles upon the water. A shield is hanged upon a pole fixed in the middle of the stream. A boat is prepared without oars, to be borne along by the violence of the water; and in the forepart thereof standeth a young man, ready to give charge upon the shield with his lance. If so be that he break his lance against the shield, and doth not fall, he is thought to have performed a worthy deed. If without breaking his lance he runs strongly against the shield, down he falleth into the water; for the boat is violently forced with the tide; but on each side of the shield ride two boats, furnished with young men, who recover him who falleth as soon as they may. In the holydays all the summer the youths are exercised in leaping, dancing, shooting, wrestling, casting the stone, and practising their shields; and the maidens trip with their timbrels, and dance as long as they can well see. In winter, every holyday before dinner, the boars prepared for brawn are set to fight, or else bulls or bears are baited."

These were the recreative pursuits to which our sturdy forefathers devoted their leisure, as far back as the year 1130. Their immediate successors breathed the same generous spirit. In the year 1222, being the sixth year of Henry III., we find, that certain masters in exercises of this kind made a public profession of their instructions and discipline, which they imparted to those who were desirous of attaining excellence and victory in these honourable achievements. About this period, persons of better rank and family introduced the play of *tennis*,[1] and erected courts or oblong edifices for the performance of the exercise.

About the year 1253, that is, in the 38th year of Henry III. the *quintan* was a sport much in fashion in almost every part of the kingdom. This contrivance consisted of an upright post firmly fixed in the ground, and having upon the top of it a cross piece of wood, moveable upon a spindle, one end of which was broad like the flat part of a halbert, whilst at the other end was hung a bag of sand. The exercise was performed on horseback. The masterly performance was, when, upon the broad part being struck with a lance, which sometimes broke it, the assailant rode swiftly on, so as to avoid being struck on the back by the bag of sand, which turned round instantly upon the stroke being given, with a very swift motion. He who executed this feat in the most dexterous manner was declared victor, and the prize to which he became entitled was a peacock. But if, upon the aim being taken, the competitor miscarried in striking at the broadside, his want of skill became the ridicule and contempt of the spectators.

Dr Plott, in his Natural History of Oxfordshire, tells us that this pastime was in practice in his time at Deddington, in that county. "They first," says he, "fixed a post perpendicularly in the ground, and then placed a small piece of timber upon the top of it, fastened on a spindle, with a board nailed to it on one end, and a bag of sand hanging at the other. Against this board they anciently rode with spears. Now as I saw it at Deddington only with strong staves, which violently bringing about the bag of sand, if they make not good speed away, it strikes them on the neck or shoulders, and sometimes perhaps strikes them down from their horses; the great design of the sport being to try the agility both of man and horse, and to break the board; which, whoever did, was accounted conqueror; for whom heretofore there was some reward always appointed."

These feats of honourable contest were succeeded by the gilded banners of exhibition, and all the long train of dependents in the interest of indolence. For the writers of these times inform us, that the soft pleasures of the stage forced the passes to public favour in the year 1391, and likewise in the year 1409; so that utility, which before stood upon the right hand of pleasure, was now ordered to withdraw for a season. The drama, it seems, was attempted by a set of useless and insignificant persons called *parish-clerks*, who, because they had the knowledge of the alphabet, ignorantly presumed that this included every other species of knowledge. The subject was truly serious, being the creation of the world; but the performance must have been ludicrous. It was, however, honoured with the attendance of noble personages; and royalty itself deigned to cast a favourable eye upon it, for the king and queen were present. These interludes lasted no longer than the time requisite for the former confederacy of utility and pleasure to resume its powers. The lance, the shield, the ball, and the equestrian procession, came forward again, and put the dramatic usurper to flight. After this period, these objects of generous pleasure seem to have had their audience of leave; and one general object, no less manly than the former, filled their stations, we mean archery. This continued till the reign of Charles I.; for we find in many hospitals founded during that reign, that amongst the articles of benefaction recorded upon their walls was this singular provision, *arms for the boys*, which signified *bows and arrows*.

There are, at this day, many places which were formerly resorted to for the practice of this noble art, distinguished by appellations which indicate their ancient usage; such as Brentford Butts, Newington Butts, and many others of the like denomination. It appears from 33 Henry VIII. that, by the intrusion of other pernicious games, archery had for a long time been disused; and to revive it this statute was enacted. It seems that the bows of the best kind were made of yew; and, that this wood might be readily obtained for the purpose, yew-trees were planted in church-yards. The sons of those only who were persons of fortune and fashion, if under seventeen years of age, were permitted to use such bows. The words of the statute are singular, and run thus: "No person under seventeen years, except he, or his father or mother, have lands or tenements to the yearly value of ten pounds, or be worth in value or moveables the sum of forty marks sterling, shall shoot with any bow of yew, which shall be bought for him, after the feast of our lady next coming, under the pain to lose and forfeit six shillings and eightpence." Upon these words two observations present themselves. One is, that the yew-wood, not being so common as other wood, might probably be soon found deficient, as it was the best wood for making bows, if the use of it had not been confined to particular ages and persons, as young people wantonly destroy what is put into their hands for useful purposes. The other observation is, that the age of seventeen is by this statute distinguished as the age of discretion, when young people are more attentive and considerate in things of private concernment. This statute makes provision of other kinds of wood for the common people; and to the intent that every person may have bows of mean price, it enacts, that every bowyer shall, for every bow that he makes of yew, make four other bows, meet to shoot with, of elm, witch-hazel, ash, or other wood apt for the same, under pain of losing and forfeiting, for every such bow so lacking, the sum of three shillings and fourpence. It seems there was a species of yew at this time called *elk*, a wood which was stronger and more pliant than the common yew mentioned in the statute, and the price of which it fixed. "Moreover, no bowyer shall sell or put to sale to any of the king's subjects, any bow of yew of the tax called *elk*, above the price of three shillings and fourpence, under the pain to forfeit twenty shillings for every bow sold above the said price."

---

[1] The word *tennis* seems to owe its origin to the French language; and if so, the game is probably of French invention. Yet the word *tenez* will hardly afford incontrovertible evidence upon this subject. For the holding or keeping possession of the ball is no part of the game, but rather a circumstance casually attending it; since, during the performance of it, the ball is in continual motion, so that there can be no *tenez* at this juncture. Perhaps some town in France called *Tennois* may have been the place where the balls were first made, and the game first introduced.

About the beginning of the reign of James I. military prowess appears to have sounded a retreat. This king, to gratify the importunity of the common people, and at the same time to obviate his own fears, published a book of sports, in which the people had some time before been indulged on Sunday evenings, but which had lately been prohibited. These sports consisted of dancing, singing, wrestling, church ales, and other profanations of that day.

Charles, his successor, wisely abolished these sports. The act of Charles states in part the several amusements, by which we may conjecture what were the remainder as stated in the book of sports by James. It is necessary to transcribe the portion of the act relating to this subject. "Forasmuch as there is nothing more acceptable to God, than the true and sincere worship of Him, and service according to His holy will, and that the holy keeping of the Lord's day is a principal part of the service of God, which in many places of this realm hath been, and now is, prophaned and neglected by a disorderly sort of people, in exercising and frequenting bear-baiting, bull-baiting, interludes, and common-plays, and other unlawful exercises and pastimes, neglecting divine service both in their own parishes and elsewhere: Be it enacted, that from and after forty days next after the end of this session of parliament, there shall be no meetings, assemblies, or concourse of people, out of their own parishes, on the Lord's day, within this realm of England, or any the dominions thereof, for any sports or pastimes whatsoever; nor any bear-baiting, bull-baiting, interludes, common-plays, or other unlawful exercises or pastimes, used by any person or persons within their own parishes; and that every person and persons offending in any of the said premises, shall forfeit for every offence the sum of three shillings and fourpence; the same to be employed and converted to the use of the poor of the parish where such offence shall be committed." All this was no doubt very proper, and showed the piety of the unfortunate monarch by whom it was enacted. But this age witnessed the close of the ancient manly sports of Britain.

PASTO, a province of Colombia, in South America, in the department of Cauca. It is the most southerly province in the department, lying next to Quito, within half a degree of the equator, and under the seventy-sixth meridian west from Greenwich. The triple chain of the Magdalena cordilleras, and the double chain of those of Quito, here unite into one mass, which is called by Humboldt the Knot of the Mountains of Los Pastos. The inhabited parts of Pasto are elevated 10,000 feet above the level of the sea. It is the Thibet of equinoctial America. As its name indicates, it abounds in excellent pastures, and consequently in cattle, and is watered by several considerable rivers. Although it is situated at a great height, yet the temperature is also high, from its vicinity to the equator; and wheat and other productions of such climates are found here. In the woods grows the tree which yields a resin called in that country *mopa-mopa*, from which the natives make a very beautiful varnish, of so durable a quality that it cannot be softened by boiling water, nor dissolved by acids. In its most northern part rises the volcano of Pasto, of which the last eruption took place in the year 1727. The principal town, also called Pasto, is situated about eighty miles south-south-west from Popayan, in latitude 1. 15. north, and longitude 76. 46. west. It is a considerable place, containing some seven or eight thousand inhabitants, who are celebrated for the manufacture of a peculiar species of cabinet-work. That portion of the grain of Pasto which is exported is principally conveyed to Popayan.

PASTOPHORI, amongst the ancients, were priests whose office it was to carry the images, along with the shrines, of the gods, at solemn festivals, when they prayed to them for rain, fair weather, or the like. In Sylla's time, the Greeks had a college of this order of priests. The cells or apartments near the temples, where the pastophori lived, were called *pastophoria*; and there were several lodging rooms for the priests of a similar kind in the temple of Jerusalem.

PATA Isle, one of the small Sooloo Islands, lying due north from Sooloo. It is inhabited, and contains a good stock of cattle; and it has also pits of saltpetre.

PATÆCI, in *Mythology*, images of gods which the Phœnicians carried upon the prows of their gallies. Herodotus denominates them πατωικοι. The word is Phœnician, and derived from *pethica*, signifying *titulus*.[1] But Scaliger does not agree in this, and Morin derives it from πιθηκος, *monkey*, an animal which had been an object of worship amongst the Egyptians, and might therefore have been honoured by their neighbours. Mr Elsner has observed, however, that Herodotus does not call the patæci *gods*; but that they obtained this dignity from the liberality of Hesychius, Suidas, and other ancient lexicographers, who place them at the stern of ships, whereas Herodotus placed them at the prow. Scaliger, Bochart, and Selden have bestowed some pains upon this subject; and Morin has likewise inserted a learned dissertation concerning it, in the *Mémoires de l'Acad. des Inscript. et des Belles Lettres*; but Mr Elsner thinks it defective in point of evidence.

PATAGONIA, or Land of Magalhaens, a very large tract of country, occupying the whole southern portion of South America beyond the united provinces of the Rio de la Plata, with the exception of portions of its western and eastern coasts, which form parts of Chili and of Buenos Ayres respectively. Its limits on the north have repeatedly been altered. In the year 1740 an imaginary line was drawn across the continent, in about 35° of south latitude, and which separated the possessions of the Spaniards from the territory of the Indians. But this boundary was never respected by either party, inroads having been repeatedly made by both into the neighbouring country. In 1822 the government of Buenos Ayres built fortresses on a frontier which extended to nearly the 38th degree of south latitude, with the intention of repelling the roving tribes from all the country which lies to the north of that parallel. The Indians, however, never recognised this line of demarcation, and made frequent irruptions into the possessions of Buenos Ayres, plundering the country, and committing dreadful havoc. From this debateable land Patagonia extends to the 56th degree of south latitude; a parallel including Cape Horn, which is in fact a small island, and the most southerly of those lying immediately contiguous to Tierra del Fuego. In longitude it extends from the

---

[1] See Bocchart's *Chanaan*, lib. ii. cap. 3.

63d to the 75th meridians west from Greenwich. Its length, including Cape Horn, is above one thousand miles; but its breadth at the widest is not much more than one third of that space, and it gradually narrows to a point at the southern extremity, where the land bends in a curve to the south-east. The interior of this vast country is but little known, only the sea-coast territory and the numerous islands having been as yet explored to any extent. Indeed, until very lately, our knowledge of any part of it, with the exception of the eastern coast, was confined to isolated and often widely-separated portions of the country; but a survey of the coasts, taken between the years 1826 and 1836, by orders of the British government, and also some recent voyages, undertaken in vessels belonging to Great Britain, the United States, and other countries, have gone far to supply this blank in geography.[1] We shall here describe the country under three heads, viz. Western Patagonia; Southern Patagonia, including Tierra del Fuego, and all the other islands; and Eastern Patagonia.

Western Patagonia. The great cordillera of the Andes, which is known to traverse the continent almost from end to end without a break, gradually decreases in elevation as it reaches the higher southern latitudes. In the neighbourhood of the equator it rises in several places more than 20,000 feet above the level of the sea; at Santiago of Chili, in latitude 34° south nearly, the highest land is 14,000 feet; farther south it continues to decline; and from the island of Chiloe to the Strait of Magalhaens,[2] Captain King estimates the average height at 3000 feet. He adds, however, that "there are some mountains which may be between five and six thousand feet high." About the parallel of 40° the coast begins to assume, and retains to its furthest extremity, a very different appearance from that which it exhibits to the northward. On the coast of Chili, and indeed along the whole of the western shore of the continent, to its northern extremity, a belt of comparatively low land interposes between the ocean and the cordillera of the Andes, and which affords but very few places of shelter for vessels. But southward of the parallel specified, the base of the mountain chain is washed by the Pacific, the waters of which, flowing as it were into the deep ravines that wind through its ramifications, form numerous channels, sounds, and gulfs, and in many instances insulate considerable portions of land. Indeed the whole western coast of Patagonia is girdled by a chain of large islands and extensive archipelagos, barren to seaward, but impenetrably wooded towards the mainland. Of these the most conspicuous are the Archipelago of Chonos, Wellington Island, the Archipelago of Madre de Dios, Hanover Island, and Queen Adelaide's Archipelago. The land of Tres Montes is however an exception, being a peninsula, and the only part of the continent, within the above limits, that is exposed to the swell of the ocean. It forms the northern part of the Gulf of Penas, and is connected with the mainland by a narrow isthmus called Ofqui, over which the Indians, in travelling along the coast, carry their canoes, to avoid the risk of passing round the peninsula, an undertaking of extreme danger. It was here that the celebrated Byron, ancestor of the great poet, and his shipwrecked companions, crossed over with their Indian guides; but the route is not much frequented, for this part of the coast, like all the rest, is very thinly peopled, and the task of pulling their canoes to pieces and reconstructing them, which is absolutely necessary, is too great to be performed, except upon occasions of extraordinary emergency.

The largest river of the coast to the south of the Archipelago of Chiloe is called San Tadeo. It is, however, of inconsiderable size, and falls into the Gulf of St Estevan, over a shallow bar, upon which there is but very little depth of water. At the head of this gulf is St Quentin's Sound, of easy access, and affording excellent anchorage. The Guaiancco Islands form the southern head of the Gulf of Penas. These are succeeded by Wellington Island, separated from the continent by the Mesier Channel, the extent of which is about 160 miles, and of course the island which it insulates is nearly of the same length; but its breadth at the greatest does not exceed sixty or seventy miles. The Mesier Channel joins the Strait of Concepcion behind the Madre de Dios Archipelago, at the Brazo Ancho of Sarmiento. About thirty miles within the Mesier Channel, Captain King says, the west side appears to be formed by a succession of large islands; and on both sides of the channel the coast is hilly, but not very elevated, there being in many places much low and generally thickly-wooded land. The same character distinguishes the Mesier from all the other channels. In this locality the trees are nearly of the same description as those which are found in all parts between Cape Tres Montes and the Strait of Magalhaens. Of these the most common are an evergreen beech, a birch-like beech, the winter's bark, a tree resembling a cypress, of which the Indians make their spears, and a very hard and heavy wood, of a red colour, which is used as fuel. A great quantity of timber grows in the vicinity of Mesier Channel, but it attains no height, and, from the humidity of the climate, is found to be decayed at the heart, and of very little use. About half way through, the Mesier Channel changes its character entirely, becoming very narrow, tortuous, and strewed with islands, whilst the land on either side rises abruptly from the water in mountainous and precipitous ridges. This character it preserves to its junction with the Wide Channel, in which the breadth increases to two miles and a half, and then running thirty-four miles with a direct and unimpeded course, falls into the Strait of Concepcion. This strait separates the archipelago of Madre de Dios from the mainland, which in this part is much intersected by deep sounds. The principal of these is called the Canal of St Andrew, and it extends to the base of the snowy range of the cordillera, which is described to be "suddenly and boldly closed by tremendous and astonishing glaciers." Sarmiento's Puerto Buono, as its name indicates, is a safe and commodious harbour, the depth of water being only nine fathoms all over, an advantage which few ports in this quarter afford. Behind Hanover Island, which is separated from the mainland by Concepcion Strait, the continent is very much intersected by extensive sounds trending deeply into the land, like the St Andrew Channel, to the base of the Andes. South of Hanover Island is Queen Adelaide's Archipelago, through which there are several channels that communicate with the Strait of Magalhaens. The principal of these, called Smyth's Channel, falls into the strait at Cape Tamar.

The general character of Western Patagonia, given by its recent explorers, is very unfavourable. Wood and water are indeed abundant everywhere; fish are easily caught; and the steamer or race-horse duck, geese, wild-ducks, and other smaller birds, are everywhere numerous; but of any other useful productions the country is quite destitute. "If," says Lieutenant Skyring, "we force a passage through the woods, it is over fallen trees and moss; if we walk over open, flat ground, we find the place a swamp; and if we climb the hills, we travel over a continuous rock, generally covered by a spongy moss, and entirely destitute of soil of any description." The forests are so dense as to be impervious to the sun's rays, so that the rain, which falls here incessantly, is never carried away by evaporation. The consequence is, that every foot of earth, and every tree and shrub, on these inhospitable shores, is always thoroughly wet. Of course the country is uninhabitable, except by savages. Clouds, wind, and rain, only cease their annoyance during the very few days on which the wind is easterly, or perhaps southerly. Probably there are not ten days in twelve months on which rain or snow does not fall, and not thirty on which it does not blow strongly. But it is mild, and the temperature is surprisingly uniform throughout the year.

---

[1] The surveying voyages to which allusion has been made, are those of the Adventure and Beagle. In drawing up our account of Patagonia, we have been much indebted to two notices of these expeditions which appeared in the Journal of the Geographical Society; the first, by Captain King, commander of the expedition, being contained in vol. i., and the other, by Sir John Barrow, in vol. vi. part ii.

[2] With regard to the orthography of this great navigator's name, Captain King says in a note, "There has existed much difference of opinion as to the correct mode of spelling this name. The French and English usually write it Magellan, and the Spaniards Magallanes; but by the Portuguese, and he was a native of Portugal, it is universally written Magalhães......I have convinced myself of the propriety of following the Portuguese orthography for a name which to this day is very common both in Portugal and Brazil."

The most striking feature of *Southern Patagonia* is the long and comparatively narrow channel called the Strait of Magalhaens, which separates Tierra del Fuego, and a great number of other islands, from the mainland. The manner in which the land, continental as well as insular, is penetrated in all directions by large and small arms of the sea, is such as to defy verbal description. The indentations frequently assume the character of immense inland seas, one of which, called Otway Water, nearly insulates a large portion of the continent, to which the name of Brunswick Peninsula has been given. A natural canal connects Otway Water with Skyring Water, which, stretching from east to west, along with another arm of the sea called Obstruction Sound, trending in a semicircle from north to south, nearly cuts off another large portion of the continent, which has been called King William IV.'s Land. The south-eastern shore of the Otway Water is high, rocky, and generally precipitous; but the northern coast is formed by low, undulating, grassy plains, wholly destitute of timber. The shores of Skyring Water have the same general character. In some parts the country is wooded, and possesses a dry and light but tolerably good soil. Captain King thus speaks of the survey which had been made of this part of Patagonia. "In this examination, the southern part of the cordillera was ascertained. The eastern shores of the interior channels were found to be low plains, with no hills nor mountains visible in the distance; and such being the feature also of the northern shores of the Otway and Skyring Waters, it is probable that all the country to the east of the sounds is a continued pampa or plain." Traces of Indians were observed, but they do not appear to inhabit the shores of these interior sounds, at least permanently. No guanacoes were discovered, but several large herds of deer were observed feeding on the shores. Sea-otters and black-necked swans in great numbers were the only other living things observed in these dreary solitudes.

"The Strait of Magalhaens," says Captain King, "being a transverse section of the continent, exhibits a very good view of its geological structure. The strait may be divided into three portions, the western, central, and eastern. The western end and centre are of primitive character, rugged, and very mountainous; whilst the eastern portion is of a recent formation, and low. The western part is composed of a succession of stratified rocks, a difference at once distinguishable by the form and nature of the ranges, and the direction of the shores; the hills are irregularly heaped together; the sounds are intricate and tortuous in their course; and the shores are formed by deep sinuosities and prominently projecting headlands. The channels also are studded with innumerable islands and rocks, which are extremely dangerous for navigation. Near the centre of the strait, the rock being clay-slate, the mountains are higher, and more precipitous and rugged in their outline, and consequently not easily to be ascended. They are in general three thousand, but some are found to be four thousand feet in height; and one, Mount Sarmiento, is upwards of six thousand feet high, and is covered throughout the year with snow. The line of perpetual snow in the strait seems to be about three thousand five hundred or four thousand feet above the sea. The strait here is quite free from islands; and it is a remarkable fact, that where the greenstone formation terminates, there the islands cease to appear." The slate formation continues as far as Fresh-Water Bay, situated about the middle of the eastern shore of Brunswick Peninsula, Cape Negro forming its northern extremity, and projecting from the narrow isthmus which unites the peninsula with the mainland. At Cape Negro the clay formation commences, and in that portion of the strait to the eastward of it the hills are remarkable for the regularity and parallelism of their direction, and their general resemblance to each other. Captain King thus concludes his geological observations: "The irregularity of the topographic features of the more western portion of the strait, combined with its confused assemblage and immense number of islands and rocks, the regularity of the strata, the coinciding parallelism of all the bays, channels, and sounds, and the total absence of islands in the central portion or slate formation, together with the remarkable similarity of the direction of the hills and coast line, and the stratification of the north-eastern tract, which is very different from that of the centre, are very striking facts, and, geologically considered, are of great interest."

The character of the vegetation is also very interesting, not so much from the variety of plants, as from their stunted growth to the westward, their luxuriance in the centre, and the total absence of trees to the eastward. This remarkable dissimilarity, of course, arises from the soil differing very much in these several localities. Light and thin in the west and east, it is unfit for plants which take a deep root; but in the centre, where there are large valleys irrigated by numerous streams, which swell in the winter months, and deposit a great quantity of alluvium, a good superficial soil is formed, and here accordingly the shrubs and plants become particularly luxuriant and productive, whilst trees of several feet in diameter are numerous. The trees are similar to those already mentioned as belonging to Western Patagonia, and they are not of much value. It is remarkable that, in this rigorous climate, the veronica, and even the fuchsia, were found in full flower within a short distance of the base of a mountain, covered about two thirds down with snow, and with a temperature of 36°. During summer, Captain King found it at night as low as 29°, yet the most delicate plants received no injury from the cold. This is singular enough; but the following facts relative to climate are still more remarkable. "I have occasionally," says this navigator, "during the summer, been up the greater part of the night at my observatory, with the internal as well as the external thermometers as low as freezing point, without being particularly warmly clad, and yet not feeling the least cold; and in the winter the thermometer, on similar occasions, has been at 24° and 26°, without my suffering the slightest inconvenience. This I attributed at the time to the peculiar stillness of the air, although within a short distance in the offing, and overhead, the wind was high." The water of the ocean near the surface is here so much warmer than the air, that in the middle of winter, which is June, a difference of no less than thirty degress has been observed, on which occasions the sea was covered with a cloud of vapour, the result of a well-known law. Parrots and humming-birds, generally the inhabitants of warm regions, are very numerous in the southern and western parts of the strait; a fact which proves that the climate is mild although the temperature be comparatively low.

Tierra del Fuego is divided into three islands by two channels or sounds. The most westerly of these is high and rugged; and although in the valleys, ravines, and sheltered nooks, there is no want of vegetation, yet, in comparison with the eastern part of the strait, it has a very dismal and uninviting aspect. It bears the appropriate name of South Desolation. To the east of it lies Clarence Island, which is only fifty-two miles in length by twenty-three in breadth. It is equally rocky with the former, but has a much more verdant and agreeable appearance. These two islands are of course surrounded by others without either number or name; and the southern and western part of Tierra del Fuego may be briefly described by stating, that deep but narrow arms of the sea intersect high mountainous islands, the summits of which are covered with snow, whilst their steep and rocky shores are more than partially covered with evergreen woods. Throughout the year cloudy weather prevails, much rain falls, and fine days are very rare. The natives, too, unlike those in other parts of the country, are an ill-conditioned race, low in stature, badly formed in body, and of a colour as dark as old mahogany. The eastern island, which is by far the largest of the three, is known on our charts by the name of King Charles's South Land. The northern part partakes of the geological character of the eastern portion of the strait; the centre is a continuation of the slate formation; and the south shore, or seaward coast line, is chiefly composed of greenstone. The eastern portion of Tierra del Fuego is a better country than any south of the forty-fifth parallel. The eastern shore towards the south part is lofty, but near the northern part it is very low. The interior is also low, with extensive plains abounding with guanacoes. The natives are a much better race of men than those in the western part of Tierra del Fuego, and the climate is also more favourable. At Port Famine, in the Strait of Magalhaens, situated in latitude 53. $38\frac{1}{4}$. south, and longitude 70. 54. west from Greenwich, Captain King took careful observations of the climate from the beginning of January till the middle of August. From his tables it appears that the mean temperature for the autumnal period, the months of February, March, and April, was 47° 2′; the maximum and minimum being respectively 68° and 28°. For the three following months, or the winter period, the mean temperature was 34° 5′, and the maximum and minimum 49° 5′ and 12° 6′ respectively. The natives of this territory are like those of Eastern Patagonia, but they have no horses. Balls, and bows and arrows, are their arms and hunting weapons. They depend for subsistence chiefly on seals, guanacoes, and birds. As a native of Tierra del Fuego is seldom out of sight of his canoe, or a wigwam, the only constructions on which he exercises his skill, some idea of these must be given. The canoe is made of several large pieces of bark sewed together. Its shape is nearly that which would be assumed by the strong bark of a tree from twelve to twenty feet in length, and about eighteen inches or two feet in diameter, when separated from the solid wood in one piece, and joined at the ends, but kept open towards the middle by means of sticks. It is ballasted by clay, and always carries a small fire. There are two kinds of wigwams, one of which is made of small straight trees, the upper ends of which are united, whilst the lower form a circle. The other is formed by branches stuck in the ground, then bent together at the top, and slightly covered with skins, bark, grass, or leafy twigs. A small aperture is left for the smoke to escape by, but here the rain as readily finds entrance.

To the south of Tierra del Fuego are a vast number of islands, the largest of which are called Hoste and Navarin Islands. The south shores of these consist of hornblende, which is the principal rock of which the islands in the neighbourhood, as well as of that of Cape Horn itself, are composed. The south summit of this small but celebrated island is situated in 55. 58. 41. of south latitude, and 67. 21. 14. of longitude west from Greenwich. With the most boisterous and humid climate on the globe, and with a low but eminently uniform temperature, vegetation flourishes here with surprising beauty and luxuriance. Some causes hitherto unexplained considerably modify the assigned law of diminution of temperature in proportion to elevation, for here it does not appear to hold true. Captain Foster, an accurate observer, says, that the character of vegetation on the mountains of Staten Island and Cape Horn did not vary in the least from that of the lowland plains. The hills about Cape Horn are very rarely covered with snow, yet, from the temperature at the level of the sea, and the known altitude of the hills, this ought to be the case.

It may be observed, that there are several other islands which lie still farther south than Cape Horn; but although clothed with vegetation, they are small, and do not appear to contain inhabitants. The vegetation of Horn Island is similar to that of Staten Island, which has been very fully described by several intelligent navigators. It is rendered remarkable by its position off the south-eastern extremity of the South American continent, by the peculiarity of its shape, it being so deeply indented by bays as to form nearly four different islands, and by the circumstance of its offering a good departure for ships bound to different parts of the Pacific, as well as a landfall for those returning from the islands situated in that quarter. It is about thirty-four miles in length from east to west, and its extreme breadth is about nine miles. Staten Island is separated from Tierra del Fuego by the Straits of Le Maire, in which there generally runs a very dangerous tide-rip. It is composed of an accumulation of lofty hills of clay-slate, separated by narrow ravines, little or no level ground being seen. The scenery of the island is wild and romantic in the extreme; and although rugged and uncultivated, it is grand and pleasing. It is clothed all over with luxuriant vegetation, consisting chiefly of beautiful evergreen trees, the most common being the antarctic beech, and a multitude of minor plants and shrubs, many of which bear excellent fruits. The seal, the otter, the rat, and the mouse, are the only quadrupeds on Staten Island; but birds are more numerous. It has long been the resort of vessels in search of seals, and they have in consequence become considerably less numerous than formerly. The climate of this island, like that of Tierra del Fuego, is extremely humid and boisterous, the sky being constantly charged with vapour. There are several harbours in Staten Island, but they are all, with one exception, confined to its northern side.

The eastern coast of Patagonia, from the entrance of the Strait of Magalhaens to the river Plata, is comparatively low. From Cape Virgins, at the mouth of the straits, to Port St Julian, in latitude 49. 15. 20. south, where porphyritic clay-stone commences, the coast is formed of clay cliffs horizontally stratified, and the country is undulating, with extensive pampas covered with grass and destitute of trees, like those of Buenos Ayres, which they otherwise resemble. "At Port St Julian," says Captain King, "the country becomes hilly, and continues so as far to the northward as latitude 44°, the rock being porphyritic. The clay formation to the southward has been likened to the appearance of the coast of Kent, and at a short distance it bears certainly a very great resemblance to it; but the cliffs, instead of being chalk, are composed of a soft marly clay, without any gravel or impressions of organic remains, excepting at Port St Julian, where fossil shells, both bivalves and univalves, are found imbedded in clay cliffs; and on the surface are lying strewed about large oyster-shells." In the clay formation there are three rivers, namely, the Gallegos, in latitude 51. 38.; Port Santa Cruz, in latitude 50. 7.; and

Port St Julian. The first does not extend farther into the interior than forty miles, and Port St Julian is of still smaller size. The Gallegos can only be entered at high water, and here the tide rises about forty-six feet, the stream being very strong. Port Santa Cruz appears to be a very considerable river. In the sketch of the surveying voyages communicated to the Geographical Society by Sir John Barrow, it is thus spoken of:—“ In a twenty days' excursion up the river Santa Cruz, we passed through a similar country, without variety, until extensive beds of lava were found overlying the whole country. We reached nearly to the eastern flank of the Andes; but, for want of provisions, could go no farther. The river was then, at two hundred miles from its mouth, almost as large, and quite as rapid, as at twenty miles from the sea. Perhaps it runs for a great distance along the base of the Andes, and so collects a great body of water; or it may run from a lake into which streams pour. Its water is not muddy. The current runs six knots an hour; none of our boats could pull against it anywhere. Its average width is two hundred yards, and its mean depth ten feet, perhaps more.” The same writer thus speaks of the country in general: “ One naturally asks why Eastern Patagonia should be condemned to perpetual sterility, while the western side of the same country, in the same parallel of latitude, is injured by too much rain? The prevailing westerly winds and the Andes are the causes. The winds bring much moisture from the Pacific, but they leave it all, condensed, on the west side of the mountains. After passing the cordillera, those same winds are very dry. Easterly winds are very rare upon the east coast; they are the only ones which carry rain to the almost deserts of Patagonia. Westward of the Andes, an east wind is dry, and free from clouds. All this country is exposed to severe cold weather in winter, and to excessive heat in summer. Great and sudden changes of temperature take place, when, after very hot weather, cold winds rush northwards with the fury of a hurricane. Even the wandering Indians avoid this region, and only cross it to get salt, or visit their burying places.” We are informed by Falconer, the Jesuit missionary, that after the dead have been interred twelve months, the graves are visited by the tribe, for the purpose of collecting the bones, and conveying them to their family sepulchres, where they are set up, and adorned with all the beads and ornaments which the friends and family of the deceased are able to collect for the occasion. The ceremony is performed by certain women of the tribe, whose peculiar office it is to attend to these rites. In corroboration of the Jesuit's testimony, Captain King informs us, that near Port Desire he had seen the graves of the Indians upon the summits of hills, but without the bodies, which he supposes to have in all probability been removed by the Indians. The Port Desire here mentioned is situated in lat. 47. 45. south, having a narrow entrance with strong tides, but affording in the offing very good anchorage, as well as shelter from the prevailing winds. Not many years before Spanish domination ceased in America, that government formed an establishment here; but, from the dry and parched nature of the land, it completely failed. Thirty miles to the northward is Cape Blanco, between which place and the Rio Negro, more than four hundred miles to the north, navigation is considered as dangerous, there being many extensive shoals, and strong tides. For an account of the Rio Negro, the most important river of Patagonia, see the article NEGRO, RIO. The Colorado, which rises near Mendoza, in La Plata, is also a very large stream, falling into the Atlantic in latitude 40. 0. nearly. It brings down a great quantity of water throughout the year, but as it does not run into any of the numerous ports near its opening, it is of no use to vessels as a place of shelter or anchorage.

The aboriginal natives of Patagonia are a tall and extremely robust race of men. Their bodies are bulky, and their heads and features large, but their hands and feet are small. Their limbs are neither so muscular nor so large boned as their height and apparent bulk would lead one to suppose; they are rounder and smoother than those of white men. Their colour is a rich reddish brown, rather darker than the hue of copper. Their heads are furnished with a profusion of rough, lank, and coarse black hair, which is tied above the temples by a fillet of plaited or twisted sinews; and they wear no other covering upon this part of their body. “ A large mantle,” says one of the recent voyagers, “ made of skins sewed together, loosely gathered about them, hanging from the shoulders to their ankles, adds so much to the bulkiness of their appearance, that one ought not to wonder at their having been called gigantic. I am not aware that any Patagonian has appeared during late years whose height exceeded six feet and some inches; but I see no reason to disbelieve the Jesuit Falkner's account of the Casique Caugapol, whose height, he says, was seven feet and some inches......Among two hundred or three hundred natives of Patagonia, scarcely half a dozen men are seen whose height is under five feet nine or ten inches; the women are proportionably tall. I have nowhere seen an assemblage of men and women whose *average* height and *apparent* bulk equalled that of the Patagonians. Tall and athletic as are many of the South Sea islanders, there are also many among their number who are slight and of lower stature. The Patagonians seem to be high shouldered, owing perhaps to their habit of folding their arms across the chest, in their mantles, and thus increasing their apparent height and bulk, because the mantles hang loosely, and almost touch the ground. Until actually measured, it is difficult to believe that they are not much taller than is the case.” This description is so precise, and, from measurements having been made, so satisfactory, that the question as to the actual size of the Patagonians may be regarded as completely set at rest. Is it more improbable that there should be races of men *above* the European standard, than it is that there should be races whose height is *below* it? Yet we know beyond a doubt that the Esquimaux are so.

With the exception of the head, little hair grows upon their bodies; and from the face it is carefully removed by shells or pincers. They do not disfigure their naturally coarse features by piercing either nose or lip, but they bedaub their body with white, black, or red paint, forming grotesque figures, such as circles around their eyes, or great marks across their faces. This ornamental body-painting is practised by all the different races of Patagonians, from Cape Horn to Buenos Ayres. On their feet and legs they wear boots made of the skins of horses' hind legs; spurs made of wood, but of iron if they can get it, balls (*bolas*), such as are used by the inhabitants of the pampas; whilst a long tapering lance, and a knife if it can be procured, complete their equipment. “ Mounted upon horses of a middle size,” says the writer already quoted, “ under fifteen hands high, and rather well bred, the Patagonians seem to be carried no better than dragoons who ride eighteen stone upon horses able to carry ten; yet they go at full speed, in chase of ostriches or guanacoes. When hunting or making long journeys, they often change horses. The women are dressed and booted like the men, with the addition of a half petticoat. They clean their hair, and plait it into two tails. Ornaments of brass, beads, bits of coloured glass, or such trifles, are prized by them. The huts of these wanderers are somewhat like gipsy tents. Poles are stuck in the ground, to which others are fixed. Over them are thrown the skins of animals, an irregular tilt-like hut being thus formed.” It is to be observed, that the inhabitants of Tierra del Fuego, and of the islands to the south and south-west, where the climate is so singularly mild, wear little or no clothing. The Patagonians appear to possess nothing like towns, but lead a wandering and unsettled life, somewhat resembling that of the Tartars.

The *Falkland* or *Malouine Islands*, being situated off the coast of Patagonia, may, in a geographical point of view, be considered as belonging to it. This group consists of two large islands and a number of small ones, some of which are mere rocks, the whole being situated between 50. 0. and 51. 20. of south latitude, nearly opposite the southern extremity of Patagonia, which is the nearest land. The two large islands, which are separated from each other by a broad channel, are called Eastern and Western Falkland; the names of the others it is unnecessary to specify. East Falkland Island is favourably situated, both for colonization and for the refreshment of vessels bound round Cape Horn. It has other advantages, such as excellent harbours, abundance of wild cattle, and antiscorbutic herbs, which point it out as a desirable resort for ships. The climate is upon the whole mild, the general range of the thermometer being in winter from 30° to 50°, and in summer from 50° to 75°. The weather is rather unsettled; but neither rain, snow, nor hail falls here in such abundance as in Southern and Western Patagonia, whilst it is free from the parching dryness of the eastern coast. The soil is good, producing spontaneously different kinds of vegetables; and wheat, flax, potatoes, turnips, and the like, have here been very successfully cultivated; but the island is destitute of trees. For fuel, peat and turf, which are abundant, are used, and also two or three species of shrubs, which are found growing all over the island. Herds of horned cattle, hogs, and horses, all wild, are plentiful; whilst rabbits, foxes, and game, especially wild geese and ducks, are extremely numerous. Fish abounds in all the bays and inlets, and those most common, when salted, are thought superior to cod. Seals are found on the island, or on the neighbouring rocks; and hair-seals, lions and elephants as they are called, abound along the shores. Many black whales have also been caught in its neighbourhood, in consequence of which the island has of late years been much resorted to by fishing-vessels belonging to various nations. The Falkland Islands were uninhabited when first discovered, and, with the exception of occasional and transient residents, have still remained so; yet their position will always render them important in the estimation of commercial nations. In the year 1766 the English formed a settlement on one of them; but it was destroyed in 1770 by a Spanish expedition from Buenos Ayres. Of late years measures have been taken by the Argentine Republic for forming an establishment here; that government laying claim to sovereignty and jurisdiction, not only over the Falkland Islands, but likewise over Tierra del Fuego, Cape Horn, and the islands adjacent in the Atlantic Ocean, as having succeeded to the sovereign rights of Spain. This claim has been resisted; but it is unnecessary to enter into the merits of what seems based on so singular an assumption. Besides, it does not appear to be very material to whom they belong; the point of importance is their colonization, which would be highly advantageous to vessels navigating these seas.

It seems highly probable that Magalhaens was the original discoverer of the southern coast of Patagonia and the northern coast of Tierra del Fuego, as well as of the strait which bears his name. Sir Francis Drake passed the strait in the year 1578; and being driven by storms to the south, discovered the western and south-western coast of Tierra del Fuego, and also Cape Horn; although the honour of the discovery of the latter has generally been ascribed to Jacob Le Maire, a Dutchman in the service of the states of Holland. In the year 1616, this navigator was the first who doubled that terminus of South America, and called it Cape Horn, after a village in Holland. Proceeding in a north-easterly direction, he crossed the strait which bears his name, and discovered Staten Island, which he so designated after the states of Holland. It is supposed that Davies, one of the companions of Cavendish, in his voyage to the South Seas in 1592, was the first person who saw the Falkland Islands; but they were not, properly speaking, discovered till the year 1594, when Sir Richard Hawkins examined them, and called them in honour of his queen and himself, Hawkins' Maiden Land. The name, however, was subsequently changed to Falkland Islands by Strong, another English navigator. During the early part of the eighteenth century, they were re-discovered by some French navigators; and hence the origin of the French name, Malouine Islands. To Captain Cook we are indebted for the first accurate account of the south-eastern coast of Tierra del Fuego, which he explored in 1774; and so little was known concerning it before this period, that when actually in sight of Cape Horn, he was unable to decide whether it was a detached island or a part of Tierra del Fuego. Amongst the other distinguished names connected with the discovery or investigation of this part of the South American continent, are those of Sarmiento (whose account of a voyage down the western coast, and through the Strait of Magalhaens, has never been surpassed), Sir John Narborough, Cordova, Byron, Willis, Carteret, Bougainville, and Weddel. To these may now be added the names of the commanders of the recent expedition, Captains King, Stokes, and Fitzroy. It only remains to be noticed, that although repeated attempts have been made to form permanent settlements in Patagonia, or upon the neighbouring islands, particularly by the Spaniards, none of these has ever succeeded. With regard to population, it must be quite obvious that no accurate idea can be formed. It has, however, been estimated at 200,000, though from what data we know not. By far the greatest part of the country, that which stretches along the eastern side of the Andes, from their base to the Atlantic Ocean, is altogether unknown, with the exception of a very few places upon the coast. It is quite possible, therefore, that the inhabitants may be far more numerous in this region than is supposed; but the general sterility of the country holds out little prospect of any great commercial advantages to be gained by intercourse with them, except in the precious metals, which are doubtless to be found in the Patagonian Andes. (R. R. R.)

PATAN, a town of Hindustan, in the province of Ajmeer, and district of Harowty, situated on the south-eastern side of the Chumbul. It is the capital of a district containing two villages, and has a handsome temple, dedicated to Vishnu, which was erected by one of the rajahs of Boondee; as also a house or palace belonging to the rajah. Long. 75. 50. E. Lat. 25. 17. N.

PATANY, a port of Asia, on the eastern coast of the peninsula of Malacca, and near the mouth of the Gulf of Siam, situated almost six miles up a river which falls into a bay and forms a good roadstead. It had formerly a considerable trade, which, however, has greatly fallen off. The Chinese now carry on the trade, which consists chiefly in the importation of European goods from Batavia, and the exportation of gold dust, canes, rattans, dragon's blood, &c. Long. 101. 40. E. Lat. 6. 50. N.

PATARA, or PATERA, a town on the sea-coast of Caramania, in Asiatic Turkey. It had in ancient times a celebrated oracle of Apollo, and still retains traces of its ancient grandeur. It is now uninhabited, only a few solitary peasants being seen wandering on the plain. Long. 29. 20. E. Lat. 36. 15. N.

PATATAN, a small town on the north-western coast of Borneo, situated three miles up the river Patatan, which has a smooth and shallow bar. It contains about 100 houses. Long. 116. 5. E. Lat. 5. 50. N.

PATAVINITY (*Patavinitas*), amongst critics, denotes a peculiarity of Livy's diction, derived from *Patavium* or Padua, the place of his nativity; but they are by no means agreed in what this alleged *patavinity* consists. According to Quintilian, Asinius Pollio taxed Livy with patavinity, though what he meant by this censure no one can now say with any certainty. Morhof believes it to consist in a singular turn of expression, and in certain phrases peculiar to the Paduese. All we certainly know about it, however, is, that it was a fault in the language of Livy, not in the sentiments or the manners. In all probability it is one of those delicacies which are no longer perceived or understood in a dead language. In 1685, D. G. Morhof published at Kiel a treatise *De Patavinitate Liviana*, in which he explains, very learnedly, both the urbanity and peregrinity of the Latin language.

PATCHOW Islands, a group of small islands, situated on the coast of China. The easternmost is Typinsan, having on its north side an extensive reef, on which the Providence, Captain Broughton, was wrecked in 1797, in long. 125. 11. E. Lat. 25. 6. N. The southernmost island is in long. 123. 52. E. and lat. 24. 6. N.

PATCOONA, a town of Bengal, and capital of a small district of the same name. It is situated on the northern shore of the Curcurry River, amongst the hills of Pacheet. Long. 87. 2. E. Lat. 23. 3. N.

PATE, in *Fortification*, a kind of platform, resembling in form a horse's shoe.

PATEE, or Pattee, in *Heraldry*, a cross, small in the centre, and widening towards the extremities, which are very broad.

PATERA, amongst antiquaries, a goblet or vessel used by the Romans in their sacrifices, in which they offered their consecrated meats to the gods, and with which they also made libations. The word is Latin, being formed from *pateo*, I am open (*quod pateat*), because it has a great aperture; in contradistinction to bottles and other vessels, which have only narrow necks, or the aperture of which is less than the body of the vessel.

The patera is also an ornament in architecture, which is frequently observed in the Doric frise, and in the tympans of arches. See Architecture.

PATERCULUS, C. Velleius, a Latin historian of considerable celebrity in the reign of Tiberius, is supposed by Dodwell to have been born before Christ 30, and to have been included in the fall of Sejanus, the favourite of Tiberius, a. d. 32. The place of his birth is unknown; but his great-grandfather, Minatius-Magius, was a native of Asculum, and took an active part in favour of the Romans during the Italic war; whilst another of his ancestors, Decius Magius, was of high rank in Campania (Pat. ii. 16). His paternal uncle, Capito, was a senator, and joined with Agrippa in accusing Cassius, the murderer of Cæsar (ii. 69). Paterculus commenced his military career under Caius Cæsar, the grandson of Augustus, and accompanied him to the East as tribune in the second year of the Christian era. On his death he attached himself to the fortunes of Tiberius, and as commander of the cavalry was present during nine years in his several expeditions in Germany, Pannonia, and Dalmatia. On his return to Rome he was raised to the prætorship, a. d. 14, the same year in which Augustus died; but he does not appear to have reached any higher dignity.

Paterculus left an abridgment of Roman history, and had promised a larger work, which it does not appear that he ever executed. This epitome was still in progress, a. d. 30, in the sixteenth year of the reign of Tiberius, and is entitled *Historiæ Romanæ ad M. Vinicium Cos. libri ii.*; but it is incomplete, as the commencement is wanting, and also a portion after the eighth chapter. Only one manuscript has been found of this author, and even that has now disappeared. It was discovered in 1515, by Beatus Rheuanus, in the monastery of Marbach, in Oberelsass, and first published at Basle in 1520. In this work Paterculus intended to give a sketch of the history of the world, more particularly of whatever he thought likely to interest the Romans. He began with the destruction of Troy, and the arrival of Æneas in Italy, and ended with the year 30 of the Christian era. He dwells particularly upon those parts of general history which were connected with that of Rome, and intersperses the work with moral reflections, that do honour to his heart and understanding. In his description of particular characters, he is more than usually happy, though his style is sometimes rather too oratorical, and evinces too much anxiety to strike the imagiation of the reader by startling thoughts and expressions. His language is generally pure, and formed upon the best models of an earlier period. Sallust seems to have been the author whose style he more particularly imitated.

The best editions are those of Burmann, edited by C. H. Frotscher, Leipzig, 1830; and of C. D. Jani and J. C. Krause, Leipzig, 1800.

PATERNO, a city of the island of Sicily, in the intendency of Catania, and district of Demone. It is situated on an inclined plain of Mount Ætna, in an unhealthy situation, near the river Garetta, 120 miles from Palermo. It contains 9880 inhabitants, chiefly employed in cultivation. Near to it are many interesting remains of antiquity.

PATERNOSTERS, Great, a cluster of shoals and islets in the Eastern Seas, which are about 120 miles in length from north-east to south-west, and thirty in breadth. Long. 117. 10. to 119. 10. E. Lat. 6. 30. to 7. 42. S.

Paternosters, *Little*. These consist of about thirteen small rocks in the Eastern Seas, between the islands of Borneo and Celebes. They are covered with trees, and have navigable channels between them; but they are surrounded with numerous shoals very dangerous to mariners.

PATERY, a hilly and woody district of Hindustan, in the province of Berar, and situated on the north bank of the Godavery River, seventy-eight miles south-east from Aurungabad. Long. 77. 8. E. Lat. 19. 18. N.

PATHHEAD, a large well-built village of Scotland, in the parishes of Crichton and Cranstoun, in the county of Mid-Lothian, ten miles and a half from Edinburgh. It consists of one long street, built upon both sides of the road leading to Kelso. The houses are generally of one story, and occupied by those engaged in husbandry, in collieries, and in furnishing the district with those necessaries which cannot be easily supplied from the capital. The population is about 1000. The parish church of Crichton is about two miles distant, and was founded in the year 1449. It is a neat little building, of Gothic architecture, in the form of a cross; and the internal arrangement is also Gothic. Near it is the magnificent ruin of Crichton Castle, which, for beauty of architecture, internal accommodation, and strength of walls and situation, is hardly to be excelled by any of the old baronial castles of Scotland.

Pathhead, a large and populous village in the parish of Dysart, in Fifeshire, Scotland. It is contiguous to the town of Kirkcaldy, being merely separated from it by a steep ascent called the Path. The village consists of three streets of plain substantial houses, inhabited by a most industrious class, who are chiefly engaged in the weaving and manufacturing of linen goods, especially of checks and ticks. There are two places of worship, one belonging to the Established Church, the other to the body of Antiburghers. An elegant and commodious school was erected a few years ago, for the free education of 150 children, by the trustees of the late Robert Philp, Esq. of Kirkcaldy, who left a large sum of money for that purpose. The population in 1831 amounted to 3330.

PATHOGNOMONIC, amongst physicians, an appellation descriptive of a symptom, or concourse of symptoms, inseparable from a distemper, and which are found in that only, and in no other disease.

PATHOLOGY, GENERAL.

The term Pathology, in its widest signification, comprehends all the knowledge which we possess relative to the state of Disease. For the facility of teaching and of studying, it has been found convenient to make various divisions of this extensive science. By the French, the terms of *external* and *internal* pathology have been employed as synonymous with what in this country are denominated the principles and practice of surgery and physic; the purpose of this division obviously being to separate the objects of medical doctrine and practice into two departments, and to assign each of these to a particular class of cultivators and practitioners. Another very important division of pathology which has long been recognised, is that into *special* and *general;* the first, or special pathology, being intended to comprehend the consideration of particular diseases, as they occur in nature; and the second, general pathology, to include, in the first place, the more general facts or principles that have been ascertained relative to the primary elements of diseases, as comprehending the *causes, phenomena,* and *effects* of the various derangements to which the animal economy is subject; and, in the second place, those more general facts or principles relative to the more obvious analogies of diseases, and the natural groups to which they admit of being referred, which medical men have deduced from the comparison of particular diseases with one another. Unlike the division into internal and external, that into special and general makes no partition of the subjects of pathological inquiry; for both survey the whole of these subjects, though under different aspects. General pathology, though in its investigation obviously resting, as we had formerly occasion to show (see article Medicine), upon a knowledge of the special, has, in teaching, been found to form a convenient and appropriate introduction to it; just as, in other sciences, it is convenient to give a general view of the principles which have been established, before entering upon the particular details the knowledge of which has led to the establishment of these principles, but of which details these principles, when once ascertained, very materially facilitate the comprehension and acquisition.

Under whatever point of view we consider the derangements of the human economy, whether, with the clinical physician, we regard them as they present themselves in individual cases, or, with the special pathologist, as constituting particular genera or species of diseases; or whether, with the general pathologist, we endeavour to reduce them to their primary elements; in each case, they offer precisely the same subjects for our investigation. These are, *first,* the morbid phenomena or symptoms by which we become aware that derangements have actually occurred in the economy; *second,* the morbific agents, by which derangements of the economy are liable to be produced; *third,* the more immediate seats of the derangements to which the economy is liable, and the peculiar nature of each of these derangements; and, *fourth,* the morbid alterations discoverable in the dead body, in those who, during life, had exhibited derangements in the performance of their functions, whether these perceptible alterations stand in the relation of cause or of effect to the derangements of function.

It is in the mode of considering these several subjects, therefore, rather than in the subjects themselves, that the distinction between general and special pathology must be looked for. In special pathology, symptoms, morbific agents, proximate causes, and organic lesions, are respectively considered in those combinations in which they give rise to, or occur in, particular diseases; and attention is directed to them only in as far as they are calculated to elucidate the natural history of the particular disease that may be at the time under consideration. In general pathology, on the other hand, the consideration of symptoms, of morbific agents, of proximate causes, and of organic lesions, or those branches of medical science which have been termed symptomatology or semeiotics, ætiology, pathogeny, and morbid anatomy, constitute so many separate portions of pathological doctrine, in which the whole of the subjects falling under each department are methodically arranged, and considered in reference to one another.

Illustration.

It may perhaps tend to place the distinction between general and special pathology in a clearer light, if we endeavour to illustrate it by a particular example.

It not unfrequently happens, that an individual exhibits a combination of *symptoms* of the following kind. He has pain in some part of the chest, his respiration is difficult, and he is subject to cough; and these symptoms, all of them obviously referrible to some derangement in the respiratory organs, are attended with others of a more general character,—with those symptoms which are denominated febrile, that is, with increased frequency of pulse, with increased heat of skin, and with disturbance of several of the other functions of the body. Now the first object of the special pathologist, in respect of this combination of symptoms, is to distinguish it as constituting a particular disease which he terms pneumonia (or inflammation of the lungs), from other combinations of symptoms which may bear a certain degree of resemblance to it,—to establish its *diagnosis,* or distinction from other analogous diseases. And even in the several cases which present the combination of symptoms that has been mentioned, the special pathologist may be able to detect certain differences of character which will lead him to establish more or fewer divisions of his particular disease; differences, for example, in the condition of the pulse, and in the characters of the pain and of the cough. Thus, of the disease in question, nosologists, or those who treat expressly of the divisions, definitions, nomenclature, and arrangement of diseases, have been led to recognise three principal forms, under the names of peripneumony, pleurisy, and bastard peripneumony. The special pathologist, in his consideration of the symptoms of pneumonia, besides distinguishing it from other diseases, and marking the more probable diversities in which it may present itself, traces its characteristic symptoms throughout the whole course of the disease, and marks the diversities which these assume in its different stages, and the other less distinguishing symptoms with which they are accompanied; in short, he applies his knowledge of the morbid phenomena, or symptoms of this disease, to determining its definition, its diagnosis, and its history.

All of those symptoms which have been mentioned as occurring in and characterizing pneumonia, fall under the consideration of the general as well as of the special pathologist; but the view which the former takes of them is considerably different from that which we have just endeavoured to sketch as being taken by the latter. By the general pathologist, these symptoms fall to be considered, not in the combinations in which they present themselves in nature, but each of them as an abstract existence, and in its relations to the other morbid affections of the organ or function of which it indicates the derangement. Thus the general pathologist has occasion to consider the symptom of *quickness of pulse,* in the general view that he takes of the different morbid phenomena which result from derangements of the function of circulation. An opportunity is thus afforded him of conisdering this symptom of increased frequency of pulse, not only in relation to the healthy state of this phenomenon, but in relation also to the other morbid states to which it is subject, whether as regards its frequency, its strength, or its regularity. By studying, in this manner, the morbid conditions of the pulse as a general pathological doctrine, medical men are furnished with a body of information of most important practical application in the investigation, not of one particular disease only, but of many different diseases. The morbid phenomenon or symptom of *cough*, in like manner, is obviously capable of being considered as a particular subject of investigation in reference to the other morbid derangements of function to which the respiratory organs are liable, and particularly in reference to the various modifications which this symptom may itself exhibit.

Secondly, a similar difference may be traced in the manner in which the special and the general pathologist consider the *morbid alterations of structure* that are discoverable in the body after death. In pneumonia these morbid alterations consist of more or less extensive marks of inflammatory action in the contents of the cavity of the chest. The special pathologist considers these morbid alterations in reference to the particular combination of symptoms that characterize pneumonia, or may accompany its progress. He examines into the condition of the contents of the chest, with a view to throw light on the phenomena which the disease exhibits during life, to trace the correspondence of the morbid appearances with the nature, degree, and progress of the external symptoms. The general pathologist likewise has occasion to direct his attention to those morbid alterations of structure to which we have alluded; but, in the view which he takes of the diseased economy, they present themselves to his attention, not, as they do to the special pathologist, in their connection with a particular disease, but as constituting one of the forms of morbid alteration of structure to which the respiratory organs are liable, the whole of which he passes successively in review, simply as a department of the natural history of the economy in its diseased conditions.

Thirdly, when the special pathologist, in endeavouring to discover the *morbific agencies* by the operation of which pneumonia has been excited, is led to ascribe its production to the influence of cold, he pays no further regard to that morbific agent, than in its relation to this particular disease; he considers merely the conditions under which cold must be applied to the economy in order to produce pneumonia, the length of time that intervenes between its application and the appearance of the symptoms, and such other points as bear directly upon the agency of the particular cause in producing the particular effect. By the general pathologist, on the other hand, this morbific agent, cold, falls to be considered as a special subject of investigation, along with the various changes that are liable to occur in the different physical conditions, and particularly in the temperature, of the atmosphere; and not as giving rise to one particular combination of symptoms or disease, but, generally, in its injurious operation on the several functions and organs of the body.

Lastly, as regards the consideration of the *proximate cause* of pneumonia, the special pathologist is led, by a consideration of the symptoms which he has observed during life, of the morbid changes which he has found after death, and of the morbific agent to which he has traced the production of the disease, to conclude that the more immediate seat of derangement is in the substance or in the membranes of the lungs, and that the particular mode in which these parts are affected is that usually termed inflammation. He is contented, therefore, with having detected the proximate cause of pneumonia as being inflammation of the lungs. But the general pathologist, in considering proximate causes as a particular department of inquiry, endeavours to go farther back in the succession of morbid changes, and to ascertain, from an investigation of the circumstances which attend the development of inflammation in different parts of the body, what are the more intimate conditions of the economy to which that morbid state is referrible, in whatever organ or texture it may occur.

Advan. tages o neral p thology

There can, we conceive, be little doubt, that a much more complete and satisfactory view must be obtained of each symptom, morbific agent, proximate cause, and organic lesion, when treated of systematically, in connection with other analogous phenomena, than when noticed incidentally in those varying combinations in which they present themselves to the special pathologist, in tracing and in describing the histories of particular diseases. And if we reflect upon the circumstances under which the several subjects of pathological investigation actually present themselves to the attention of the student of pathology, in the consideration of a particular disease,—morbid functions, morbid structures, morbific agents, and proximate causes of disease, all of them combined in one whole, the relations of the several parts of which it is necessary for him, as if intuitively, to comprehend,—it must be obvious, that unless he shall previously have had an opportunity of taking a systematic view of each of these branches of pathological inquiry by itself, such as is afforded in the study of general pathology, he cannot fail to be lost among the multitudinous and imperfectly understood matters which, simultaneously, as it were, press themselves upon his attention.

The pathologist, indeed, is in a great measure in the same situation as the chemist, who meets in nature, for the most part, with objects which consist, not of one, but of several different elements, and which have been produced and are maintained in their combinations by the action, not of one, but of several different forces. To be able to understand the constitution of such a compound object, and the share which each physical and chemical force has had in its production and maintenance, it is necessary that the chemist should be well acquainted with those elements into which compound bodies are found to be reducible. And he must also be acquainted with those few powers or forces which, by their operation on the several elements of matter, enable it to enter into those multitudinous combinations that give rise to the great diversity of substances of which the globe consists. In short, the special pathologist has to do with particular diseases, the general pathologist with the elements of diseases—elements which can be ascertained only by analytical examination, founded on long-continued observation and experience; but a knowledge of which, when once acquired, is of primary importance in those synthetical operations by which the special pathologist endeavours to arrive at the establishment and distinction of particular diseases.

Topics be not

The limits which we are obliged to prescribe to ourselves in the following article render it impossible to take a satisfactory view of the various subjects which fall under the province of general pathology; and, at the same time, we are unwilling to occupy the pages of this work with a bare enumeration of the topics which, in a systematic consideration of this department of medical science, would properly claim our notice. We shall confine ourselves, therefore, to some general observations relative to the state of disease; the distinctions between this state and that of health; the primary seats of diseased actions or diseased conditions in the animal economy; and the more essential differences existing among those simple pathological states, morbid conditions, or primary elementary derangements in the structure and functions of the different parts of the human economy, on which the series of morbid phenomena constituting particular diseases depend—those states, in short, to which the name of proximate causes of disease has very generally been applied. The topics which we have now enumerated are those the consideration of which is usually included under the branch of general pathology termed *Pathogeny*. A slight view of them, we hope, may be rendered both interesting and instructive to general readers; and, at the same time, will prepare the way for a review of the difficulties to which medical men are exposed in endeavouring to determine, in individual cases, the nature of the maladies with which their patients are affected, which we purpose to sketch in the article Physic, Practice of.

D nitions of sease.

V bal.

The first duty of the pathologist seems obviously to be, to define that which professedly forms the object of his inquiries and speculations, viz. the state of disease. The definitions of this term, which have been proposed by pathologists, have differed, not only in the precise language in which they have been expressed, but in the general principles on which they have been constructed. Some have been merely what are called verbal definitions, that is, substitutions of synonymous expressions; such, for example, is the definition which represents disease as a change from the natural to a preternatural state, natural and preternatural being nothing more than synonymous expressions for healthy and diseased. It is needless to insist on the obvious fact, that no possible benefit can result to medical science from definitions of this kind.

Fr n sup- po final ca

In others of the definitions that have been given of the term disease, an attempt has been made to found this upon the supposed final cause of the phenomena which that state presents. Thus disease has been said by some pathologists, including the illustrious Sydenham, to be an extraordinary effort undertaken by nature, for the purpose of throwing out from the system, by the motions excited, some morbific or noxious matter, and of thereby averting from it death and corruption. The attempt to establish the final cause of any phenomenon obviously implies a persuasion of our being acquainted, as far as the particular object is concerned, with the views and intentions of the Author of nature, in obedience to whose will the universe is conducted. The ends or purposes of some of His arrangements seem sufficiently obvious to justify us in deducing them; but there are others of these arrangements in which this is far from being the case, and in attempting to establish the final causes of which, we run the risk of substituting some crude conception of our own minds for the wisdom of the Creator. That there is great risk of doing so in respect of disease, might easily be established, by the various and even contradictory views of its end or purpose which have been taken by those who have endeavoured to derive their definition of this state from its final cause.

rom sup- ose real sse e.

In a third set of definitions of the term disease, an attempt has been made to explain what has been called its real essence; as when disease has been said to consist in a disproportion of the four humours, or in an excess or deficiency of the principle of excitability. It would be easy to show that the definitions of disease which have been framed upon the principle of explaining its real essence, have varied with the prevailing medical doctrine of the period in which they have been proposed, inasmuch as they have necessarily borne a relation to the views entertained by medical men respecting the powers by which the functions of the human economy are carried on in the state of health, in whichever of the various forms of mechanical, chemical, animistic, or vital doctrines, these powers may have been sought for.

From enumeration of obvious characters.

How, then, is disease to be defined? Precisely, it is conceived, upon the same principles that every other object which admits of definition ought to be defined. By an enumeration of circumstances obvious to all, and acknowledged by all, to appertain to it; an enumeration not depending for its reception on the speculative opinions of the person to whom it is addressed, but recognised as valid, whatever decision we may come to on certain controverted points of physiological or pathological doctrine; whether, for example, we suppose the functions of the animal economy to be executed conformably to, or in a manner subversive of, the physical and chemical laws of inorganized matter; whether we admit or reject the agency of a rational soul, or that of a peculiar principle of life, in regulating its healthy and morbid phenomena; whether we affirm or deny that dynamical derangement must in all instances be preceded by organic alteration; whether or not we suppose mental derangement to be in all cases dependent on corporeal affection; and whether or not we admit that the fluids may be the primary seats of disease. Health and disease must be defined in reference to one another. It is certainly the occurrence of disease that suggests to the mind the idea of health; but this idea is the rule or standard by which we fix our notions of the state of disease. They are both states of living beings; and the respects in which they differ seem to be, that in the state of health living beings maintain their ordinary structure, and are capable of exercising all their functions with ease, regularity, and harmony; whilst in the state of disease there is an obvious change in the structure or organization of some of the solid parts of which the living beings consist, or in the composition of some of their fluids; or there is a considerable deviation from the easy, regular, and harmonious performance of one or more of their functions.

This definition, it is conceived, is applicable to any being, or class of beings, of which health and disease can be predicated. The structure of living beings is more or less complicated, and the functions they perform are more or less numerous, according to the place they hold in the scale of organized existence. Consequently the number of particulars falling within the two terms, health and disease, must vary. In the human subject these terms must be understood as having reference to the exercise of the mental faculties or functions, as well as of the corporeal; but the definitions above suggested are, we conceive, equally applicable to the simplest and to the most complicated of organized beings. The definition which we have given of disease makes provision also for those slighter diversities in the manner in which different persons, or the same persons under different circumstances, exercise their functions, which, though not consistent with perfect health, are still too inconsiderable to amount to absolute disease; diversities which are usually included by pathologists under the term of the latitude of health.

Proximate causes of disease.

Having pointed out the principles which should guide us in the definition of the term disease, and the elements of which that definition should consist, we shall now proceed to offer some general observations on what are called the proximate causes of diseases, or, in other words, those morbid states or pathological conditions of the different portions of the economy to which the morbid phenomena or symptoms of diseases are ultimately referrible. As we had formerly occasion to advert to the relations in which symptoms and proximate causes stand to one another, we shall not at present dwell on this subject farther than to remark, that general readers as well as students of pathology are exceedingly liable to be puzzled by the great variety of synonymous terms which have been employed by different pathologists to designate respectively the proximate causes of diseases, and the concourses of symptoms to which they give rise. Thus Professor Sprengel, in his *Institutiones Medicæ*, iv. 19, with the purpose of marking the distinction between these two distinct constituent parts of disease, has proposed to employ the term "*morbus*," or disease, to denote the internal morbid condition or proximate cause, and the term "*affectio*," affection or passion, to mark the attendant combination of external symptoms. "Whatever," he remarks, "is perceptible by the senses of the patient himself, or of his attendants, is to be considered as the passion or affection, but the internal state is the true disease." By others of the German pathologists, and particularly by Gmelin of Tubingen, and by the late Professor Hartmann of Vienna, it has been proposed to mark the same distinction between the internal morbid states and the external symptoms of diseases, by the employment of the terms *disease*, and *form of disease;* the term disease being applied by them, as it is by Sprengel, to the morbid or pathological condition or conditions of the economy in which particular diseases essentially consist; whilst, by the term form of disease, they wish to designate the combinations of morbid phenomena occurring in concourse and succession which manifest themselves in the progress of particular diseases, and which Sprengel has included, as we have just seen, under the ambiguous and equivocal term of "affectio." Besides the terms to which we have alluded, a considerable variety of other appellations have been employed more particularly to designate the internal morbid conditions of the economy considered as the states on the existence of which, singly or in combination, the phenomena or symptoms of particular diseases depend. For in different pathological works these internal morbid conditions are treated of under the various appellations of primary elements of diseases, primary morbid states or pathological conditions, and of simple morbid affections or simple diseases (morbi simplices). Chomel speaks of them as the essences of diseases; they form the internal morbid conditions of Broussais, the simple affections, the internal alterations, and common principles of diseases, of Buffalini; and the "*internæ indoles morbi*" of Friedlander. Some pathologists have denominated them *pathological*, in contradistinction to *nosological* diseases; the term nosological being applied in the same sense as the "*morbi forma*," or form of disease, of the later German writers, to those combinations of morbid phenomena or symptoms occurring in concourse and succession, by which particular diseases are externally manifested and are characterized in our systems of nosology.

May comprehend a succession of events.

In speaking of the proximate cause of any disease, it is necessary to keep in recollection, that under this title may be comprehended everything that goes on in the economy between the application to it, or action upon it, of the morbific agent which disturbs its physiological or healthy condition, and the manifest derangement of function which results. Frequently the change from the healthy to the morbid state does not consist in a single event, but in a succession of events. Thus, when the effect of a blow inflicted upon the head is to induce the concourse of symptoms that are comprehended under the nosological disease apoplexy, the first effect may have been the rupture of an artery within the cranium; as a consequence of this rupture there occurs an extravasation of blood; and, as a consequence of this extravasation, a particular state of the brain, whether or not we may admit it to be of the nature of compression. We may regard all this series of events combined, as constituting the proximate cause of the apoplectic attack; or we may restrict this term either to the last event in the series which we are able to trace as preceding the production of the symptoms, or to the event or change which first succeeds to the operation of the morbific cause.

Seats of proximate causes.

A curious topic of inquiry relative to those primary morbid states or pathological conditions which constitute the proximate causes of diseases, relates to their seats, or the parts of the economy in which the changes from the healthy to the morbid condition, on which the production of morbid phenomena or symptoms depends, may occur.

Organic and dynamic.

We formerly noticed the division of proximate causes into the organic or structural, and the dynamic or functional (article Medicine). This is a division as to the propriety of which much disputation has taken place amongst pathologists. If it were to be understood as drawing an absolute line between pathological states arising out of altered conditions of the organic structure of the different textures, systems, and organs of the body, and pathological states arising out of altered conditions of the properties or powers by which the functions are executed, independently of any altered conditions of the organic structure, the distinction would obviously be fallacious. The properties or powers by which the functions of the body at least are performed, have no existence independently of its material organization. And accordingly we cannot conceive any change to occur in the condition of these properties, without its being preceded by a corresponding change in the condition of the material organization. The proper signification to be attached to the terms organic and dynamic proximate causes seems, therefore, to be, that in the former there occurs an *apparent* alteration in the structure of some part of the frame; whilst in the latter, no alteration of structure is *discoverable*, the change in the condition of the material organization being of too subtile a nature to be appreciable by the senses.

Corporeal and mental.

The next question relative to the seats of the proximate causes of diseases that presents itself for consideration is, whether, when the mental functions betray evidence of a deranged performance, this is to be considered as having its primary origin in morbid conditions of the mind itself, or in changes, perceptible or imperceptible, in the material organization. It is allowed on all hands, that it is by no means infrequent, in cases of mental derangement, to find marks of organic alteration of structure in the brain, whilst in other cases no such appearances are discoverable. Of these dissimilar, not to say contradictory results, those who contend for and those who oppose the dependence of mental derangements on morbid conditions of the material organization are equally prepared to give explanations. Those who oppose this dependence aver that when morbid appearances are present, they are to be regarded as concurrent effects of the condition which produces the symptoms of mental aberration, and not as the causes of the mental disturbance; and hold that the independence of mental upon bodily derangements is proved by those cases in which all appearance of organic alteration is wanting. The pathologists who contend for this dependence allege, on the other hand, that whatever may be thought of the morbid appearances observable in the first class of cases, it is quite possible to conceive respecting the second, that changes in the material organization actually exist, although they are of too subtile a nature to be discovered; in short, that mental derangements may be dependent on dynamical and not on structural alterations of the material organization.

Setting aside, then, as inconclusive, the arguments deduced on either side from the results of anatomical investigations, the opposed partisans appeal to the morbific agents by which mental derangements are liable to be induced, and to the means by which their removal is best promoted, for corroboration of their respective views. The advocates for the independence of the mind refer to cases in which mental derangement has been produced or removed by moral or purely mental causes; whilst the advocates for its dependence allege that almost every morbid affection of the mind succeeds to the action of certain physical and vital causes, which can be supposed to operate on the mind only through the intervention of the organization, and particularly of the brain; and they enforce the importance of attention to the state of the corporeal organs in the treatment of insanity. This contrariety of opinion obviously rests on the opposite views that have been propounded relative to the connection of the mind and the body in the state of health; a subject into which we feel indisposed here to enter, not from the apprehension that any conclusion at which we could arrive regarding it would be inconsistent with that belief in the future existence of the soul which forms the groundwork of all religion, but from a conviction that it is a question to the solution of which the human faculties are incompetent.

There is still another question relative to the seats of the proximate causes of diseases, which it is necessary for the general pathologist to consider and determine, viz. it being admitted that the different fluids of the body are liable to morbid alterations in their physical and chemical qualities, whether such morbid conditions of the fluids are capable of constituting in themselves real proximate causes of diseases; or, in other words, whether the fluids are ever the seats of those morbid conditions or pathological states on which the external phenomena or symptoms of diseases depend.

Against the supposition of morbid conditions of the fluids ever being the proximate causes of diseases, it has been argued, first, that the morbid alterations to which they are liable depend on previously existing morbid conditions of the solids, and are to be regarded in the light of effects rather than as causes. When, for example, the secretion of the kidneys contains some of its ordinary constituents in undue proportion, or contains an element not usually found in it, this morbid condition of the urine, it is urged, must be supposed to depend on a previous morbid condition of the kidneys. To estimate the force of this argument, it is necessary to consider the fluids of the body as belonging to two classes; first, the blood, and the fluids out of which it is formed, the chyme and chyle; and, second, the fluids formed out of the blood, including the various secretions, as the saliva, the bile, the urine, &c. Now, without any morbid action of the organs of digestion, and merely in consequence of the introduction of unsuitable food into the stomach, we may suppose the chyme and chyle, and consequently the blood into which they are converted, to be vitiated. Again, in passing through the lungs, the blood may be acted on in such a way as to produce important changes in its physical and chemical constitution, by elements contained in the inspired air, and independently of any morbid condition of the solids. The blood being vitiated in either of the ways supposed, or in others that might be mentioned, the fluids secreted from it may be conceived to participate in its noxious qualities likewise, without any previous morbid condition of the solids. But if, on the other hand, the blood be in a healthy state, and the fluids formed from it be diseased, we must suppose this to depend on some morbid condition of the secretory organ, whether of a structural or dynamical character. From this view it appears that morbid states of the fluids, though they in some instances proceed from morbid conditions of the solids, in others occur independently of any such conditions.

But it has been argued, secondly, that when there exists any noxious principle in the fluids, and particularly in the blood, whether preceded or not preceded by morbid conditions of the solids, it is not immediately on the altered state of the blood, but on a change which it induces in the solid parts, that any morbid phenomena or symptoms which manifest themselves depend; that the blood serves merely as a vehicle for bringing certain noxious agents in contact with those parts on which they most readily exert their action; so that the blood, when it has undergone any morbid alteration, ought to be regarded rather in the light of a remote or occasional, than as a proximate cause of disease. Thus, for example, when, in consequence of extirpation or disease of the kidneys, urea accumulates in the blood, this acts as a poison upon the nervous system. Here, it is said, the blood can only be regarded as a vehicle of the urea, which acts as a morbific agent upon the brain; and it is in the brain that the change takes place which constitutes the proximate cause of the comatose affection that succeeds.

In this argument a fact seems to be overlooked, to which we formerly adverted, viz. that between the first action of a morbific agent upon some part of the economy, and the manifestation of those phenomena or symptoms which ultimately result, there usually occurs a *succession* of morbid changes. Is the term proximate cause to be understood as embracing the whole of these changes, or as being confined to one only? and if to one, does it apply to the first change which we can detect as being produced in the economy, or to the last of the series which we are able to trace, as immediately producing the development of the symptoms? If we include the whole series of changes under the term proximate cause, then morbid states of the fluids must, we conceive, be admitted as forming a constituent element of some proximate causes. Or if we restrict the term to the change in the economy that is first produced, then we must admit that this occurs frequently in the states of the fluids. So that it could only be by restricting the term proximate cause to the last change which we are able to trace in the economy, previously to the manifestation of the symptoms, that we could be supposed justified in denying that morbid conditions of the fluids act occasionally as the proximate causes of diseases.

The question, whether preternatural conditions of the fluids, and of the blood in particular, can be regarded as capable of constituting the proximate causes of diseases, or indeed are themselves entitled to the appellations of morbid or diseased states, has been supposed to depend on the judgment that may be formed relative to the vitality of the fluids, or their possession of life; it being argued, that unless endowed with life, they cannot be subjects of disease. There seems to us to be great fallacy in this argument. We cannot concur in the physiological doctrine which would represent life as a peculiar property, with which certain bodies are endowed; nor are we any more disposed to regard it as a single definite result. The phenomena of the human economy are no more effected by the agency of a single property, power, or force, than are those of a steam-ship; and it would, in our estimation, be as reasonable to suppose that the admission of a *principle of propulsion* is necessary and sufficient for the explanation of the latter class of phenomena, as that the former can be explained by the assumption of a *principle of life.* The propulsion in the one case, and the life in the other, are the effects of the conjunct operation of several properties or powers, and do not constitute in themselves either simple powers or simple results. The expression of the life being in the blood, seems to be obviously a metaphorical expression, of the same character as would be a poet's invocation to steam as the principle of propulsion.

We shall now proceed to take a summary view of the different forms of morbid states, pathological conditions or proximate causes, from the existence and operation of which severally, or more or fewer in conjunction, in the different parts of the human economy, the various concourses of symptoms, or nosological diseases, to which that economy is subject, seem to originate. We shall, in the first place, pass in review organic or structural proximate causes, or, in other words, the visible morbid changes that are discoverable in the physical and structural conditions of the different textures, systems, organs, and cavities of the body.

Organic proximate causes.

The greater degree of attention that is now bestowed on the examination after death, of the morbid changes which are liable to take place in the structure of the different parts of the body, must be regarded as one of the circumstances that most strikingly distinguish the medical investigations of the present period from those of former times. Indeed, the result of these investigations has been the creation of an entirely new branch of medical science, designated by the name of pathological anatomy, a branch the knowledge of which is every day becoming more and more important, from the discoveries that are continually making in it, and from the light these discoveries have a tendency to throw upon the phenomena, the nature, the effects, and the treatment of diseases. It may justly, indeed, be said, that it is to the zeal and success with which morbid anatomy has been cultivated during the last half century, that we principally owe the recent rapid progress and advancement of pathological knowledge, and much of all that is most solid and exact in medicine considered as a science.

Pathological anatomy has been said by the late Professor Lobstein, in his work on that subject, to have three objects to accomplish. In the first place, it describes the changes which occur, in regard to the position, form, size, and intimate structure of each organ in the state of disease, and considers every such organ in its relations to the other parts with which it is connected by more or less immediate sympathies. The second object of pathological anatomy is to explain, as far as this may be possible, the morbid changes that occur in different organs; to point out the manner in which these changes are effected; and to ascertain under what influences, and according to what laws, they are produced. These inquiries comprehend all questions relative to the origin, formation, and development, of organic diseases. In the third place, it is the province of pathological anatomy to compare organic alterations with the morbid phenomena or symptoms that manifest themselves during the course of a disease, to analyse these phenomena with care, and to determine to what degree they are dependent on the alterations of structure by which they are accompanied.

It is in the second of these points of view only that we have occasion at present to consider this department of medical science, as elucidating the origin, formation, and development of the various visible structural alterations which occur in the different organs of the body. As the morbid changes of structure that are liable to occur in different parts of the body are all referrible to a certain number of specific elementary forms, which exhibit the same general characters, in whatever textures or organs they may be seated, great advantage is derived from studying these elementary forms of morbid alterations of structure abstractedly, before proceeding to consider them as they are observed to occur in the particular organs of the body. This view of the elementary forms of diseased alterations of structure might, perhaps, without impropriety, be considered as forming a branch of pathogeny, the more peculiar province of morbid anatomy being, as we conceive, to consider, what Professor Lobstein has marked out as its first object, the primary morbid changes as taking place in the structure of each of the different textures, systems, and organs of the body individually.

The morbid changes of structure that occur in the different textures and organs of the body may be temporary, disappearing after a longer or shorter period of time, and leaving the parts which they attack in their original healthy condition. Hence it is that in many diseases not of a fatal nature, it is only from death occurring accidentally during their continuance, or in a short time after their termination, that we have an opportunity of ascertaining the morbid changes of structure by which they are accompanied. In other instances, again, the morbid changes are of a more permanent nature, and when the disease in the course of which they arise does not prove fatal, they may either continue to exist without materially disturbing the economy, or they may prove the cause of new diseases.

Pneumatosis.

The first physical change in the condition of the body to which we shall allude, as giving rise to morbid phenomena or symptoms, is the presence of air in situations in which it does not naturally exist, or its excessive accumulation in situations in which it is usually met with. This occurrence it has been proposed to designate by the name of Pneumatosis. The presence of air in the subcutaneous cellular substance, sometimes occurring as a consequence of injury, and in other instances independently of injury, has been long known to surgeons by the name of emphysema. In the sacs of the pleuræ, a quantity of air occasionally collects, producing great disturbance of respiration, an occurrence to which the name of pneumo- or pneumatothorax has in recent times been applied. It is well known, too, that in some cases of sudden death occurring during surgical operations, air has been found in the cavity of the heart. In the cavity of the alimentary canal there is always present a quantity of air or gas, but under certain circumstances the quantity becomes greatly augmented, giving rise to the state of the abdomen termed by medical men tympanites. It belongs to the general pathologist to ascertain the different seats in which a preternatural accumulation of gases is liable to occur, and their chemical characters in these various situations; and to endeavour to determine the sources from which, in each situation, they may be supposed to have been derived; whether the particular form of pneumatosis under observation has depended on the introduction of atmospheric air by natural or accidental passages; on the putrefactive decomposition of solid or fluid substances; on mechanical obstruction to the free passage of gases in parts which naturally contain them; on the perforation of organs naturally containing gases, and the consequent escape of these into other parts; or whether a gas is ever exhaled from the surface of a cavity or canal in the human body in consequence of diseased action.

Anæmia.

A second change that sometimes presents itself to those engaged in tracing the pathological conditions of the body, and one which, according to its particular seat, may give rise to the symptoms of various diseases, is a deficiency of blood either in the vascular system generally (in which case its most obvious indications are to be found in a peculiar paleness of the face, and particularly of the lips and of the gums), or in the vessels of some particular textures or organs. To this state medical men give the name of anæmia, or bloodlessness. It belongs to the general pathologist to inquire into the various situations in which anæmia is liable to be met with; and into the circumstances in which it may be supposed to originate, whether from absolute deficiency, or from vitiated qualities of the nutritious fluid.

Congestion.

A third morbid condition, which gives rise to symptoms of much importance and of considerable variety according to the particular seat which it may occupy, is the reverse of that last mentioned, consisting in a turgescence of the whole, or of particular portions of the vascular system. This is the morbid condition which medical men have denominated congestion, and to which the terms active or passive are affixed, according as it is supposed to depend on an increased propulsion of blood into a particular texture or organ, by the powers which maintain the circulation; or on an obstruction, which prevents the blood that has been sent to a part in due quantity, from being returned with proper freedom to the heart. When the state of vascular turgescence is general, in consequence of an excessive production of blood, the vascular system is said to be in a state of plethora; so that plethora is general congestion, and congestion is partial plethora. When the blood is sent to some particular part of the body in increased quantity, without the morbid condition of inflammation being produced, or, in other words, when there occurs active local congestion, English pathologists apply to this morbid state the name of determination, and French pathologists that of fluxion. It forms by no means an unimportant object of pathological inquiry, to determine the characters by which local congestion occurring during life may be distinguished, in the examination of dead bodies, from similar appearances originating during the agony of death, or subsequently to that event, principally in obedience to the laws of dead matter.

Another morbid condition, and one nearly allied to congestion, is that in which the contents of the sanguiferous system escape from the vessels in which they circulate, and are discharged either on the surface of a cavity or canal, or into the substance of an organ. This constitutes the state termed hæmorrhage. We have examples of hæmorrhage occurring on the surface of a cavity or canal in the discharge of blood from the lungs, termed hæmoptysis by medical men, or from the stomach in hæmatemesis; and of hæmorrhage occurring into the substance of an organ we have examples in many cases of apoplexy, in which a larger or smaller quantity of blood is discharged into the substance of the brain. Like congestion, hæmorrhage may be active or passive, that is to say, it may depend either on the blood being propelled into a particular texture or organ in greater quantity or with more force than is usual, or on some obstruction to its return to the heart. To that state of the sanguiferous system on which active hæmorrhage depends, pathologists give the name of the *molimen hæmorrhagicum.* It belongs to the general pathologist to inquire into the various seats in which hæmorrhage is liable to occur; the conditions of the blood, and of the blood-vessels on which it may be supposed to depend; the modes in which the blood escapes from the vessels in cases in which no visible solutions of continuity can be detected; whether this takes place by dilatation of open terminations of blood-vessels, or what is usually called sanguineous exhalation; or whether by dilatation of pores in their coats, a theory of hæmorrhage which is intended to be expressed by the terms sanguineous transudation. The changes which extravasated blood produces on the surrounding tissues, and those which it itself undergoes in various situations subsequently to its being extravasated, constitute inquiries of very considerable importance to the pathologist, particularly the question, whether, in any instances, extravasated blood is capable of becoming organized.

In the state of health there occurs an effusion of a watery fluid into the cellular texture lying beneath the skin, or entering into the composition of parenchymatous organs, and into those cavities of the body which are lined by serous membranes; but the removal of this fluid by absorption seems to go on as rapidly as its secretion, so that the quantity never becomes considerable. In disease, however, an accumulation of watery or serous fluid is liable to occur in the various situations that have been mentioned, producing a pathological state which has long been known to pathologists, under the name of dropsy, as a fertile source of morbid phenomena. It has been supposed that an accumulation of serous fluid occurring in disease, might depend either on the secretion being increased without a proportionate increase in the power of absorption, or on a diminished power of absorption not attended with a corresponding diminution in the power of secretion. It is well ascertained, that in a large proportion of the cases in which dropsical effusion occurs, there exists, as in passive congestion, an impediment to the free return of the blood to the heart. Such, for example, seems to be the case in those organic diseases in the course of which dropsy is so apt to supervene, such as the organic diseases of the liver, or of the heart itself. An impediment to the capillary or venous circulation does not however appear to be essential to the production of dropsy. In certain inflammatory conditions of the membranes by which serum is naturally secreted, dropsical effusion is liable to take place, constituting what may be called inflammatory or active dropsy; and it would appear from modern investigations, that in certain diseased conditions of the kidneys, dropsy occurs, without there being any reason to suspect mechanical impediment to the capillary or venous circulation. Under certain circumstances, an effusion of a serous fluid takes place from membranes of a mucous character; but in this case the fluid, instead of accumulating in the body as in serous dropsy, is discharged externally.

Inflammation.

There is no morbid state to which the economy is liable, of greater importance, in respect of the number of diseases of which it serves as the foundation or which it complicates in their progress, or in respect of the severity of these diseases, and the frequency of their occurrence, than that of inflammation. Every thing combines to prove that it is in the capillary vessels that this morbid state has its immediate seat; but much diversity of opinion subsists among pathologists as to the precise condition of these vessels, in respect of increased or diminished action, in the state of inflammation. From its frequent occurrence on the surface of the body, as in inflammation of the skin or of the eye, the phenomena of inflammation are more generally known to non-professional readers, than those of any other morbid condition to which the body is subject. But the pathologist is aware that these phenomena undergo very considerable modifications, according to the texture in which the inflammation may happen to occur.

The state of inflammation sometimes disappears entirely from an organ or texture that has been affected by it, leaving in them no trace of its having existed. In this case it is said to undergo resolution. Sometimes, again, it becomes associated with, or leaves behind it, various morbid conditions, which have been denominated the terminations, local effects, or consequences of inflammation. Of these terminations, some manifest themselves in the effusion either of an increased quantity of the fluids that are naturally secreted, or in the formation of preternatural fluids from surfaces, or into the substance of organs. When boiling water, or a blister, is applied to the skin, the scarf-skin, in a longer or shorter time, rises in vesications; and if it be pierced, a quantity of watery fluid exudes. This is an illustration of inflammation terminating in an effusion of serum. If a part of the body be removed by a cutting instrument, and after a short time the surface thus produced be examined, it will be found to be covered by a glutinous fluid. Again, if a fluid be injected into the cavity of the abdomen, the serous membrane which lines that cavity, and covers the intestines, will in no great length of time be found coated with a similar glutinous matter. These are examples of the termination of inflammation in effusion of coagulable lymph; an occurrence, as we shall presently see, of equal importance, whether we regard its salutary or its noxious effects in the economy. Every one knows, more or less, what is meant by an abscess, viz. a collection of what is called purulent matter in some texture or organ of the body. The effusion of purulent matter, whether into the substance of an organ or texture, or on the surface of a membrane, is uniformly preceded by inflammation, and constitutes what is denominated its suppurative process, or termination in suppuration.

In many instances, the state of inflammation is followed by the removal or disappearance of a larger or smaller portion of the substance of the body, in consequence of a morbid absorption. We have illustrations of such a morbid absorption, first, in the formation of ulcers on the surface of the body; this may be called *ulcerative* absorption: second, in that process by which an abscess that may be seated at a considerable depth from the surface of the body, gradually approaches towards it, and at last is discharged externally; in which and similar cases, the absorption is said to be *progressive*: and, third, in the mode in which parts of the body that have become dead are separated from the living, or what has been called *disjunctive* absorption.

The death of a part is another event which is liable to occur as a termination of inflammation, particularly when very intense in its character. This state has been variously designated. By applying to the whole progress of this consequence of inflammation, from its commencement to its conclusion, the name of mortification, pathologists are enabled to mark out two important stages, the first extending to the period when the mortified part loses its vitality, which stage has been named gangrene; and the second designating the state in which the part is perfectly dead, the stage or state of sphacelus.

As some of the terminations of inflammation are destructive, so others of them are reparatory. We have already noticed the effusion of coagulable lymph as being frequently of this character. If the two surfaces of an incised wound covered with coagulable lymph be brought into apposition, they will adhere, and in a short time become united by the passage of blood-vessels from one surface to the other. This is called the termination of inflammation in adhesion. But if the surfaces of a wound be not brought into apposition, the layer of coagulable lymph effused upon them will in a short time exhibit a number of granular eminences, which acquire a bright red colour, from their becoming penetrated with blood-vessels. To this process is given the name of granulation. In a longer or shorter time, the granular surface becomes covered with a bluish-white layer, and being considerably diminished in extent by its own contraction and the elongation of the surrounding integuments, it comes to be again skinned over, or, in the language of surgeons, it undergoes cicatrization. Similar processes take place in the interior parts of the body. Should a person on the serous surface of whose bowels an effusion of coagulable lymph has taken place, survive the violence of the inflammatory attack, the lymph, in becoming organized, will produce adhesion of the different folds of intestines to one another, and to the inner surface of the walls of the abdomen; and an ulcer on the inner surface of the stomach or intestinal canal may undergo the processes of granulation and cicatrization, just in the same way as an ulcer on the skin.

Alterations of consistence.

In the progress of the various inflammatory processes which we have enumerated, the different textures and organs in which they occur are liable to undergo alterations in their consistence, becoming in some cases harder, and in other instances softer, than natural. There seems reason to believe, however, that these changes of induration and softening sometimes occur in particular organs or textures, independently of any inflammatory action, and simply from morbidly increased interstitial deposition, or morbidly increased interstitial absorption. Much attention, for example, has recently been paid to a state of softening occurring in the brain, in cases in which there is no reason to believe it to have been connected with inflammation. A peculiar softening of the coats of the stomach, first particularly noticed by Mr John Hunter, and attributed by him to the solvent action of the gastric juice after death, has been supposed by some pathologists to be a product of disease, taking place during life, and characterized by a peculiar concourse and succession of symptoms. As softening is a change liable to occur in the putrefactive decomposition which the different parts of the body undergo after death, considerable care is requisite to avoid confounding pseudo-morbid with truly morbid softening of the textures.

Alteration in amount of substance.

The different textures and organs of the body sometimes undergo an alteration in the amount of their natural substance, capable of modifying very considerably the exercise of their functions, and consequently of constituting the proximate causes of diseases. Sometimes the substance of the texture or organ is in excess, in which case it is said to be in a state of hypertrophy. In other instances there occurs a diminution in the amount of substance, or what has been called atrophy, or, more properly, perhaps, oligotrophy. Every one is aware how much the bulk of the voluntary muscles depends upon the degree of exercise to which they are subjected. A similar principle is applicable to the involuntary muscles; and accordingly it is found, that when by any cause impeding the free motion of the blood in either circulation, the action of one or other ventricle of the heart requires to be performed with increased vigour, it takes on the state of hypertrophy. The same change is liable to occur in the urinary bladder when there exists a mechanical impediment to the discharge of its contents. Under certain circumstances, one of the kidneys becomes incapable of effecting its natural secretion. In this case, the bulk of the organ very frequently diminishes, or, in other words, the kidney passes into a state of atrophy; whilst its neighbour, taking upon itself, as it were, the duties of both, becomes enlarged in bulk, or passes into a state of hypertrophy. The only explanation we are able to give of the production of this class of organic changes is, that the nutritive vessels of the texture or organ which experiences them act with increased or with diminished vigour.

New formations.

In a large number of cases of morbid alteration occurring in the different textures and organs of the body, there is found replacing more or less of their natural substance, or disseminated through it, a substance of a nature entirely foreign to it. Sometimes this new or foreign substance resembles more or less closely one of the natural textures of the body, as when a mass of fat, or portions of cartilage or of bone, are formed in situations which they do not naturally occupy. To such productions of natural textures in preternatural situations the name of homoioplastic formations has been applied. In other instances, the new formations consist of substances altogether foreign to the natural organization of the body, as when masses of hard or of soft cancer (the *scirrhus* and *fungus hæmatodes* of pathologists) are developed in one of the various situations in which they may occur. Such formations receive the general denomination of heteroplastic. Various other divisions have been made by pathologists, of the different new growths to which the textures, systems, and organs of the body are subject, according as they are symptomatic or idiopathic, cystic or sarcomatous, &c.; but that which is perhaps of most practical importance is, their division into the mild and the malignant. The latter of these terms is applied to such new growths as manifest more or fewer of the following characters; first, that at no period of their development are they susceptible of resolution, that is, of being removed by natural processes of the economy; second, that they are very apt to appear in different textures and organs of the body simultaneously, or in succession; and, third, that when they are removed by operation, growths of the same character are very apt to recur in the same situation, or to develope themselves in some part not previously affected. It is obvious, that in the production both of the homoioplastic and of the heteroplastic formations, the nutritive vessels of the part must be supposed to secrete a matter different from that which they habitually furnish; with this distinction, that in the first class the secreted matter is analogous to that which the same vessels in the state of health furnish to other textures, whilst in the second, the matters are totally different from those formed in any part of the economy in a healthy condition.

Homoioplastic.

Heteroplastic.

Entozoa.

The morbid products that have hitherto been mentioned as occurring in the different parts of the body, are either inorganized, as in the cases of pneumatosis, dropsy, and some of the new growths; or, if organized, it is by a vascular communication with the body in which they exist. But it sometimes happens that separate living beings are met with in different textures and organs, constituting what by naturalists are termed entozoa. The entozoa most familiarly known are intestinal worms, which, as every one is aware, give rise to a great variety of morbid phenomena or symptoms. Sometimes the entozoon, instead of having the general characters of a worm, consists of a nearly transparent bag filled with serous fluid, in which case it is termed an hydatid. The disease occurring in sheep, named the sturdy in some parts of this country, depends on the existence of hydatids in the brain; and entozoa of the same generic character have now been found in the substance of almost every organ and tissue of the human body, and even in the fluids contained in the transparent cavities of the eyeball. Entozoa are different from any species of animals that are found *out of* living bodies; and nothing is more perplexing to naturalists than to explain the manner in which they are produced and propagated. It has been ascertained that some genera and species of entozoa are confined to particular animals, whilst others are distributed pretty widely over the animal kingdom.

Co cre- tio .

It sometimes happens that a secreted fluid deposits a portion of the solid matter which it contains, and this by accumulation comes to form one or more masses of various dimensions, which may either remain in the situation in which they were first formed, or may make their way into other situations. These masses, of which we have examples in the depositions that occur from the urine, from the bile, from the saliva, and sometimes even from the tears, are called concretions, calculi, or stones, by pathologists. A singular form of concretion is not unfrequently met with in certain veins of the body, particularly the uterine and pelvic, to which, from their position, the name of phlebolites has been given. In these several instances, we may suppose the deposition to have depended either on a deficient quantity of the dissolving menstruum in which the solid matters were contained, or on an excess of the saline, &c. ingredients; or it may in some cases have depended on the presence of a foreign ingredient in the fluid, producing precipitation of some of its natural principles. In the alimentary canal, concretions are occasionally formed by an agglutination of matter introduced along with the food, and the viscid secretions of the mucous surface of the stomach or intestines. Thus it has been found, that in those districts in which oatmeal forms a large portion of the diet of the labouring classes, such concretions are liable to be formed by the inner beards of the oats; and an excessive employment of magnesia as an antacid medicine has been known to produce an analogous result. In horses, alvine concretions, formed chiefly out of their food, sometimes attain a very large size; and in those animals which are in the habit of licking with their tongues their own hides, or those of their young, balls of hair, curiously fashioned, are very frequently met with.

Alte ions of ca city.

Sometimes the several hollow organs of the body, without any appearance of change in the textures of which they consist, are found to have undergone an alteration in their capacity, which may either extend over a considerable portion, or be limited to a single point. In some instances the cavities or canals referred to are more capacious than natural, or in a state of dilatation; in other instances they are less capacious than natural, or in a state of contraction; and sometimes contraction occurring in the course of a canal may approach, if not amount, to obliteration. Contraction, as occurring in a canal, constitutes simple organic stricture. It not unfrequently happens that the states of contraction and dilatation are met with in different parts of the same organ; for if a portion of the alimentary canal, for example, become contracted, so as to retard the passage of its contents through it, the portion above the contraction will be very liable to become dilated by distention. The arteries are liable to undergo two different forms of dilatation, the one consisting in a preternatural and permanent enlargement of the whole circle of the canal, the other in a partial or lateral distention of its coats. To a dilatation of the second kind the name of an aneurismal sac is given by pathologists, and much controversy has existed as to the conditions of the coats of the vessels in which it is formed. Permanent dilatation of the veins, produced by the accumulation of blood in their cavities, constitutes what has been called varix. In some instances contraction at a particular portion of a canal, or stricture, seems to be congenital. Of this there is a curious illustration in a contraction that has been repeatedly met with in the aorta, or great artery of the systemic circulation, at a very short distance from its origin in the heart. Congenital stricture, sometimes amounting to obliteration, is not unfrequently met with at the lower extremity of the intestinal canal.

Dila ion.

Cont - tion d oblite - ion.

Alterations in position.

Very serious morbid phenomena occasionally result from textures or organs having undergone changes in their natural position. Thus it sometimes happens that a portion of the lining membrane of the gullet is protruded between the layers of muscular fibres which surround it, and in this way a pouch or bag is produced, which may occasion great impediment to deglutition. Again, it sometimes happens that a portion of the intestinal canal slips down, as it were, into the portion immediately below it, forming an *invagination*, as it is termed, and causing, so long as it lasts, more or less obstruction of the bowels; or a portion of bowel may escape from within the cavity of the abdomen, through an aperture, natural or preternatural, in its parietes, constituting what surgeons term a *rupture*, or *hernia*, and requiring, in many instances, the performance of a delicate surgical operation for its replacement or *reduction*. To alterations in the relative position of the parts constituting a joint, viz. the socket, and the lever which moves upon it as a fulcrum, surgeons, as is well known, give the name of *dislocations*.

Malformations.

Lastly, morbid phenomena are found to be referrible, in some cases, not to any structural alterations occurring in the progress of life, but to imperfections in the original organization of the individual,—to what are called malformations or monstrosities. These imperfections or malformations seem sometimes to consist in the absence or incomplete development of a particular organ or set of organs, as if the natural process of development had been arrested or retarded during the early stages of the growth of the fœtus. In other instances they consist in reduplication of one or more of the parts of the body; and in others, again, the process of development seems to have taken a perverted or vicious direction, so as to produce anomalies not referrible to either of the two heads that have just been mentioned. Of malformations compatible with life, but laying a foundation for disease, we have examples in certain conditions of the heart, and large vessels immediately connected with it, which allow a portion of the blood to pass from the right side of the heart to the left, without passing through the lungs, and consequently without undergoing that depuratory process which it is the purpose of respiration to effect. In this case the extremities of the fingers, the lips, and other external parts of the body, have more or less of a blue colour, giving rise to the affection denominated cyanosis, or blue disease.

Such seem to be the principal sensible alterations that are liable to occur in the animal frame, and which, as giving origin to various combinations of morbid phenomena or symptoms, we regard as proximate causes of diseases.

Dynamic proximate causes.

We have, in the next place, to consider those proximate causes of disease, pathological states, or morbid conditions, which are not attended with any sensible alterations in the textures or organs of the body, recognisable during life or after death; and the occurrence of which is inferred solely from the disturbance that takes place in the exercise of particular functions. Thus, under certain circumstances, the action of the heart may become irregular, and yet after a time resume its wonted regularity, showing that no *organic* alteration had occurred in it; or this fact may be still more decidedly established, in case of accidental death, by the actual inspection of the parts. The secretion of the kidneys may, in like manner, be very materially altered in respect of its quantity or composition, without these organs having undergone any discoverable change in their anatomical constitution. In our inability to refer such derangements of function to perceptible organic changes, we attribute them to changes or alterations in the peculiar powers, forces, or principles, with which the parts are endowed, that enter into the composition of the texture or organ the function of which is deranged; and it is in this respect that these derangements are properly termed *dynamical.*

In judging of the *structural* changes which disease is liable to induce in the several textures, systems, and organs of the body, it is obviously of primary importance that we should be well acquainted with their healthy structure and appearances, and with the changes which these are liable to undergo subsequently to death, from putrefactive decomposition, and other causes. The more extensive and accurate our knowledge of these matters becomes, the better must we be qualified to recognise the presence of structural alterations, and to determine in what they actually consist. In like manner, in considering the *dynamical* derangements which are liable to occur in the human economy, it is essential to have determined what powers are concerned in the production of its various healthy phenomena. The full consideration of this subject obviously falls under the province of the physiologist; but as it is one respecting which considerable confusion of ideas seems to us to prevail, and the correct determination of which is not less important to the pathologist than to the physiologist, we shall venture to offer a few remarks with regard to it.

In entering on this inquiry, it is necessary to keep in mind, that all the phenomena of the human economy, as far as they are corporeal, are produced by the reciprocal action of certain external agents, and of the different parts of the organized frame, upon one another. It is necessary also to keep in mind, that all which is meant by ascribing to any substance the possession of a particular property, is, that when a certain other substance is present, a particular change will take place in the condition of one or other, or of both of them. In stricter language, we substitute the term *susceptibility* for that of property, in those cases in which the change is most obvious in the substance to which we ascribe the property; and we use the term *power* in those cases in which the change is most obvious in the substance that is brought into relation with that to which we ascribe the property. It is equally a property of water to be solidified by a certain degree of cold, and to dissolve salt; but, in accurate expression, susceptibility is applicable to water in respect of the former, and power in respect of the latter, of these phenomena. When the pathologist, therefore, speaks of derangements or diseased conditions of the *powers* or *properties* of the human economy, as contrasted with morbid conditions of the structure of the body, he does not mean to allege that changes have taken place in certain mysterious agencies or spirits lurking in certain textures of the body; but he means that changes not recognisable by our senses have occurred in these textures, in consequence of which they differently affect, or are differently affected by, external agents, from what is habitual to them. It is of these differences in the mode of affecting and of being affected that we, by observation, obtain a knowledge; and it is by reasoning back from these that we infer the occurrence of those changes in the conditions of the particular textures of the animal frame, of which, in the application to them of the term dynamical, we avow that we cannot obtain any more direct information.

Understanding the term power in this signification, we may remark, that it is not peculiar to organic textures to undergo changes in their powers or properties, without any perceptible change of their interior physical conditions. When a bar of iron, on being struck with a hammer, is rendered magnetic, or deprived of its magnetic power, according to the direction in which it is previously placed (see the article MAGNETISM), no change can be detected in the characters of the mass, or of the particles of which it consists. The only knowledge we obtain of any change having taken place in the bar of iron, is derived from its evincing or not evincing magnetic properties.

What, then, are the properties concerned in the production of the various phenomena of the human economy, so far as these are of a corporeal nature?

The learned and the unlearned all concur in recognising a particular class of beings under the title of living or organized, and in distinguishing this from another class of beings, which they designate as inorganized, lifeless, or dead. There is likewise a pretty general concurrence in acknowledging that the prominent characters or outstanding phenomena by which living beings are distinguished from those that are dead, are, *first,* the conversion of foreign matters into their own substance, which is continually going on within them; and, *second,* their invariably taking their origin from a part which had previously belonged to another being of exactly the same nature with themselves. For accomplishing these two ends (the processes of assimilation and reproduction, as they are termed), it is found that certain determinate series of phenomena are executed by living beings, to which the name of vital or organic functions is assigned, such as the functions of circulation, of respiration, of secretion, &c. The question, therefore, as to the properties concerned in producing the various corporeal phenomena of the human economy, resolves itself into the inquiry, what powers or agencies are concerned in the execution of each of these vital functions? Are the phenomena of which each of them consists, and which, as has been said, result from the reciprocal action of external agents, and of the different parts of the body, on one another, when analysed and separately examined, of the same nature as the phenomena observed to occur in the inorganized world; or are they of a nature specifically distinct from these; or is there a correspondence in some and a diversity in others? It is on the determination of these questions, obviously, that our judgment must be founded, how far it is necessary to attribute to the different parts of the body powers, principles, or properties, distinct from those of inorganized matter, or, shortly speaking, vital or organic properties, since such properties, if recognised, can be considered only as general expressions for determinate groups of phenomena, identical in themselves, and different from any which can be observed to occur in the inorganized world.

And here we may remark, that, in modern times particularly, there has very generally prevailed among physiologists a great disinclination to admit an identity in the various phenomena of living beings and resembling phenomena of inorganic matter; or, in other words, to admit the operation, in the production of the phenomena of living beings, of those physical and chemical properties to which the various mutations that dead matter is liable to undergo are usually ascribed. Accordingly, physiologists very generally maintain that the agencies by which the characteristic phenomena of living beings are produced, are essentially different from those on which the phenomena of inorganic matter depend. It is not denied that there is a general correspondence in the material phenomena exhibited by the two classes of beings; that in each of them there is evidence of the occurrence both of motions in the sensible masses, and motions in the insensible elements, of matter, —of both physical and chemical changes. But there is a great disposition to allege, that notwithstanding this general correspondence, there exist such special differences between the physical and chemical phenomena of organized and of inorganized bodies, as to render it necessary to admit the operation, in the production of the former, of powers or properties distinct from those which operate in producing the latter; that vital physics and vital chemistry are distinct sciences from inorganic physics and inorganic chemistry, acknowledging different and even contradictory laws. Before proceeding to consider what grounds actually exist for this strong disinclination to recognise the operation in the animal economy of the physical and chemical properties of inorganic matter, we may remark, that it may probably be traced in a great measure to two sources, *first*, the abuse of physical and chemical explanations of the phenomena of the animal economy which was practised by the mathematical and the chemical sects of physicians; and, *second*, the wish which the cultivators of any branch of knowledge generally entertain to establish for it an independent character. It is not impossible that, in the present instance, this latter feeling may be increased by the pride of man rendering him averse to recognise an identity, even in his corporeal operations, with those of brute matter.

The opinions of physiologists respecting the operation in the corporeal functions of the human economy, of powers different from those which regulate the changes of inorganic matter, may perhaps be advantageously reduced to the three following heads.

1*st*, That all the phenomena of this economy are under the guidance of a single property, by whatever name this may be designated, which is capable of subverting, and indeed is in a perpetual struggle with, the physical and chemical laws of inorganic matter.

2*d*, That each function of the economy is under the guidance of a particular or special principle; and,

3*d*, That in certain animal textures, independently of, or superadded to, the physical and chemical powers of inorganic matter, there are implanted powers specifically distinct from these, which have an important share in the production of most or of all the phenomena of the animal economy.

To the two first of these doctrines there present themselves objections of precisely the same nature. They confound complex with simple results; and refer to the agency of a common power, a number of phenomena which, though they may be considered as all tending to a common end, are widely different in their essential nature from one another. The function of respiration, for example, comprehends a number of distinct phenomena, some physical and some chemical, understanding by these terms respectively the motions of the sensible masses and of the insensible elements of matter; and to suppose that science can be advanced by attributing all this variety of phenomena to the agency of a common principle, is a strange deviation from the ordinary laws of philosophical inquiry. If this observation be just in regard to one function, it must certainly acquire additional force the greater the number of functions, and consequently the greater the diversity of phenomena, the production of which is referred to the agency of the supposed principle.

The advocates of the third doctrine recognise the important influence of those physical and chemical powers to which the phenomena of inorganic matter are attributed, in producing the phenomena of the several functions of the animal economy, so far as these are corporeal. But an analysis of these functions leads them to believe that, besides the inorganic powers, there must be others concerned in their production, seeing that some of their phenomena are of a nature specifically distinct from those exhibited by any form of dead matter. They do not content themselves with the general conclusion that the function of digestion, for example, is totally different from any process which occurs in inorganic beings, and that it is consequently incumbent upon us to admit the existence of a peculiar vital principle of digestion; but analysing, as far as they are able, the various phenomena which, in combination and succession, constitute this function,—tracing the series of antecedents and consequents by which it is effected,—they endeavour to determine what are the precise phenomena which do, and what are those which do not, admit of being referred to the ordinary properties of inorganic matter, and are thus led to judge what phenomena, from not being referrible to these properties, require the recognition of powers peculiar to living beings in general, or to the animal economy in particular.

There are obviously two sources of error in the judgments which may be formed on these points. 1*st*, Our imperfect knowledge of the phenomena respecting which we are called on to judge; our inability to trace the successive series of changes by which the obvious result is ultimately effected. How much of the knowledge requisite for enabling us to refer the phenomena of digestion, to resume our former example, to their respective causes, is of very recent attainment? how much perhaps still remains to be acquired? But, 2*d*, our knowledge of the laws which preside over the physical and chemical changes of inorganic matter is likewise still very imperfect. There are doubtless very many phenomena going on in the inorganic world, which have not even been observed, far less generalized. These may have their resembling phenomena in the economy of living beings; and, from our ignorance of the one, we may fail to observe the other; or, in observing them, we may erroneously suppose them to depend on principles or properties peculiar to the economy in which they present themselves to our notice. The observations and experiments of Mr Brown respecting the motions of molecular particles, those of Dutrochet relative to Endosmosis and Exosmosis, and those of Professor Graham relative to the transmission of gases, have brought to light in our own days a number of phenomena occurring in the inorganic world, which may very possibly have their resemblances in the economy of organized beings; and other sources of motion and change in inorganic matter may yet remain to be discovered. And even in respect of those physical and chemical agencies, with the operation of which, in the inorganic kingdom, we are more or less familiar, it is quite possible that they may be taking a share in producing the phenomena of organized beings, though we do not recognise their operation. Thus a very strong belief has been entertained by many physiologists that electricity or galvanism exerts a very important influence in the performance of several of the functions of the animal economy; and that, in like manner, as this economy possesses within itself the power of generating *heat*, so it is provided with an apparatus capable of evolving electricity or galvanism. It is not necessary to enter here into a consideration of the circumstances which have led to the belief that the brain is such an apparatus, and the nerves the conductors of the electrical or galvanic fluid. But we may suggest, that if this opinion could be proved to be correct, many of those phenomena which seem at present irreconcileable with the ordinary properties of inorganic matter, and consequently to require the recognition of peculiar vital powers, might find their explanation in the agency of this powerful source of physical and chemical changes.

If these views relative to the powers concerned in producing the phenomena of living economies be correct, it follows, that it is the duty of the pathologist, in tracing the dynamical derangements to which the different parts of the animal frame are subject, to keep in mind the variations which may occur in the ordinary physical and chemical properties of the solids and fluids of which that frame consists, as well as in those properties which are peculiar to itself; seeing that modifications of these inorganic principles must necessarily have great influence in inducing pathological phenomena.

With this caution we shall now proceed to consider what are the ultimate or simple phenomena occurring in the animal economy, which seem to be specifically different from phenomena observable in the inorganic kingdom, and to require the recognition of peculiar vital properties, and to what pathological conditions these properties seem to be subject. The vital properties most usually recognised by physiologists and pathologists seem to be Irritability, Tonicity, Sensibility, Nervous Energy or Innervation, Sympathy, and Vital Affinity.

Muscular irritability.

Whatever differences may exist in the views which physiologists entertain respecting the other agencies by which the various functions of the animal economy are executed, they universally agree in admitting muscular irritability, or the power which muscular fibres possess of shortening on the application of certain agents, which physiologists term *stimuli*, as a property of great influence in the production of the physical motions observable in the economy, and as one to which nothing strictly analogous, so far as is known, has been discovered in any other portions of nature's works. There are few, indeed, if any, of the corporeal functions of the animal economy, natural, vital, or animal, in the exercise of which muscular fibres, and the principle of irritability with which they have been endowed, are not more or less immediately concerned. And, consequently, the dynamical morbid conditions of these fibres, or the morbid conditions of the principle of irritability, enter largely into the explanations which the pathologist endeavours to give of the derangements to which the different organs of the body are liable in the exercise of their functions.

Its morbid conditions.

The deviations from healthy action to which the principle of irritability is subject, seem referrible to three principal heads, viz. *first*, increased, *second*, diminished, and, *third*, perverted or vitiated action.

Excessive or deficient, in facility;

In respect of irritability, physiologists distinguish between the *facility* and the *force* with which muscular fibres contract, or the *mobility* and *vigour*; and the same distinction must be kept sight of in pathology. Irritability may be excessive in *facility*, or, in other words, muscular fibres may be excessively *mobile*, a slight stimulus producing a contraction to which it would have been quite inadequate in health; or irritability may be deficient in *facility*, or muscular fibres preternaturally *immobile* or *torpid*, a stimulus which would have called a muscle into action in the state of health being now insufficient to effect this. Of preternatural mobility of muscular fibres we have an example in the readiness with which, in particular states of disease, the muscular coats of certain canals, as the gullet and urethra, are excited to contraction by the introduction into these canals of foreign bodies which, in their healthy state, would pass through them without exciting any perceptible muscular contraction. Of preternatural immobility or torpidity, throughout all its possible degrees, we have examples in the state of palsy, both in the voluntary muscles and in involuntary muscular organs.

in force;

Again, irritability may be excessive in *force*, a given amount of stimulus producing a more forcible contraction than in health; as frequently happens to the voluntary muscles in cases of mania, when the patient manifests a degree of physical strength greatly beyond his natural powers; and as seems to occur in respect of the action of the vascular system on the circulating blood, in what is called the phlogistic or inflammatory diathesis. Irritability may likewise be deficient in force, as is well known to happen to the voluntary muscular system in some diseases, as fevers at a very early stage of their progress, and as happens in all diseases, sooner or later, in the course of their progress. Of deficient force of irritability in involuntary muscular organs, we have an example in the action of the sanguiferous system in the state of collapse, or sinking.

It may be remarked, that the states of diminished force or vigour, and increased facility or mobility of contraction, are frequently combined in the same muscles or muscular organs; so that although a small amount of stimulus is sufficient to call them into action, their action is not powerful. This fact is often exemplified in the contractions of the heart, which may be very frequent in number, and at the same time very feeble in force.

Vitiated.

Besides increased and diminished force and facility of action, there are other morbid conditions to which the power of muscular irritability is liable, that may be referred to the head of altered or vitiated action. In the ordinary circumstances of the economy, the contraction of a muscle, succeeding to the application of a stimulus, is speedily followed by a state of relaxation, and this even though the stimulus which produced the contraction continues to be applied.

Spasm.

But there is a morbid state of the contraction of muscles that is not disposed spontaneously to alternate with relaxation, and in which, too, the fibres do not easily yield to any extending powers that may be applied. Such a state of contraction, which may occur either in voluntary muscles, or in involuntary muscular organs, is called a state of spasm. Most persons have had experience of those local spasms which, under various circumstances, occur in the muscles of the extremities, particularly of the calves of the legs, and to which the name of cramps is familiarly given. That singular affection which has been termed catalepsy, in which a part of the body retains for a great length of time the position in which it may be placed, however disagreeable or fatiguing it might be to the person when in health, furnishes us with an example of a tendency to spasmodic contraction pervading the whole of the voluntary system of muscles. The various muscular canals, as the gullet, the intestines, the gall-ducts, the urethra, &c. are frequently the seat of spasmodic affection, producing an inorganic form of *stricture*.

Convulsion.

A second morbid condition of irritability that may be referred to the head of vitiated or altered action, is that in which muscles and muscular organs are excited to contraction by preternatural causes, and are contracted with unusual velocity and force, and in which, especially, the contractions alternating with relaxation are frequently and preternaturally repeated. Contractions of this kind are observable in the greater part of the muscles of voluntary motion, in the fits or paroxysms of the disease termed epilepsy; and to the same class belong the agitatory motions observable in different parts of the body in chorea, or St Vitus's dance, and in hysteria. These contractions have sometimes been called *clonic* spasms, whilst the epithet of *tonic* spasms has been applied to contractions not alternated with relaxations. But the terms tonic and clonic spasms are now very generally laid aside by pathologists, and the two different kinds of muscular contraction formerly designated by them are now usually distinguished from one another by the simple names of spasms and convulsions. Though spasm and convulsion be in themselves distinct phenomena, it would be easy, by a reference to particular diseases, to illustrate the truth of Dr Cullen's remark, that "many, and indeed most, of the diseases considered as spasmodic affections, are, in respect of tonic and clonic contractions, of a mixed kind." (Sect. 1753.)

Vl expility.

A wide difference of opinion has subsisted among physiologists as to the nature of the power by which the relaxation of a muscle succeeding to its contraction, consequent on the application of a stimulus, is effected; some conceiving that a sufficient explanation of this phenomenon is to be found in the simple elasticity of muscular substance, whilst others maintain that it can be accounted for only by recognising in muscles an active power of expansion as well as of contraction. Nor is it muscular tissue only which has been supposed to be endowed with an active principle of expansion or dilatation. By many the expansion which is liable to occur under peculiar circumstances, in what has been called the erectile tissue, is supposed to have its primary origin in an active distention of that tissue itself, and not in its mere passive dilatation by fluids propelled into it from behind, or accumulating in it in consequence of obstruction to their further course (Chaussier, Adelon, Stieglitz, &c.): whilst by others it is conceived, that to explain the state of *orgasm*, as it is called, we must pre-suppose the existence of an increased vital affinity between the blood and the tissue of the organ which is capable of distention (Müller). The phenomena in question are certainly highly deserving of investigation; but we confess we are not at present prepared to acknowledge the necessity of admitting a peculiar vital property as being concerned in their production.

Tocity.

Many physiologists have admitted the existence in the animal economy of another form of contractile power besides irritability, distinct from any observable in inorganic matter, to which they have given the name of tonicity. There has been great vagueness, however, in the attempts which have been made to define the peculiar characters of this property, so as to distinguish it from the elasticity of inorganic matter on the one hand, and from muscular irritability on the other, as well as to determine by what textures it is possessed.

Supsed pro of its exince.

Many phenomena seem to prove, that in living and healthy animals, the muscular fibres, both of the voluntary muscles, and of involuntary muscular organs, have a constant tendency to become shorter, and, but for counterbalancing powers, such as antagonist muscles or distending liquids, would actually become so. Thus, if any joint be bent by external force, the flexor muscles contract spontaneously without any exertion of the will. If a muscle be divided transversely by the knife of the surgeon, a considerable degree of retraction takes place in the separated portions, and the antagonist muscle also contracts. That the retraction in this latter case is not attributable to the stimulus of the knife, appears from the fact, that "the separate portions which have been retracted," as Mr Mayo remarks, "if excited, shorten further, and then again become elongated to their last dimension." Besides, when the tendon of a living muscle is cut across, the muscle instantly contracts, and continues of its diminished length. In fracture of the patella, the rectus muscle of the thigh contracts sometimes to a very great extent; and in most cases of fracture there occurs similar retraction, which, though it may be in part explicable by the irritation of splintered pieces of bone, cannot be wholly attributed to that cause. It is found, also, that the arteries are always nearly accommodated to the quantity of blood contained in them. When a ligature is placed upon an artery of a living animal, the part of the artery beyond the ligature becomes gradually smaller, and is emptied to a certain degree, if not completely, of the blood it contained. It has been observed, too, that some hours after death the arteries are much diminished in size, and this occasionally to such an extent as to be rendered impervious.

By some physiologists it has been imagined that these phenomena may be explained on the principle of simple elasticity, it being conceived that in the living body muscles are stretched out or extended beyond their natural state as dead elastic substances. "To the elastic nature of the muscles generally," says Dr Bostock (*Elem. Syst. of Physiology*, i. 160–1), "as consisting of a compound of fibre and membrane, I should refer the *natural contraction* of Whytt, those actions which Cullen, and many physiologists since his time, have called tone or tonicity, and which Bichat has classed under the head of contractility from texture, in which, after a part has been distended by any cause, when the distending force is withdrawn, it gradually recovers its natural form and dimensions." But the supposition that muscles are stretched, in the living body, beyond their natural elasticity, is opposed by the fact, that when a dead muscle is cut out of the body, before it has begun to putrefy it will be found to extend farther than from its origin to its insertion, as is particularly evident in a long muscle, such as the sartorius.

There are other circumstances, too, which seem to show that this constant tendency of muscular fibres to contract depends on their connection with the nervous system, on a constant and regular action of the nervous system on the muscular, a fact which does not seem reconcileable with the notion of its being simple elasticity. When the portio dura (or muscular nerve) of one side of the face is divided, the muscles of the opposite side of the face contract to such a degree as to draw the cheek of the affected side over to it; and the same thing is liable to occur as a consequence of cerebral apoplexy. It is usual to explain this phenomenon by saying that the muscles of the affected cheek, having lost their tonicity, no longer counterbalance those of the sound side, which, in consequence, being left to the uncontrolled influence of their own tonicity, undergo contraction; nor does there appear to be any mode of accounting for it, either on the hypothesis of simple elasticity or of irritability. We may perhaps also regard the pathological condition of relaxation of the sphincter muscles occurring in particular states of the nervous system, as evidence of the dependence of tonicity upon that system. It is proper, however, to keep in mind a fact which seems to have been ascertained by Bichat, viz. that when a muscle is transversely divided, the retraction is equally prompt and energetic, whether the nerves of the part have been previously cut through or not.

If, then, we recognise irritable contractility and tonic contractility, or irritability and tonicity, as two distinct vital properties, the following seem to be the characters by which they must be distinguished from one another: *First*, tonicity is the tendency which certain parts of the animal frame have to contract, independently of the agency of stimuli; irritability is the tendency of muscular fibres to contract in consequence of the agency of stimuli: *second*, the contractions dependent on irritability are alternated with relaxation; those dependent on tonicity are not so alternated. As a *third* distinctive character, it has been alleged that while the contractions of irritability are instantaneous, those arising from tonicity are very gradual and slow.

Application to pathology.

While the existence of tonicity as a separate power has been a matter of considerable doubt and discussion to physiologists, the language that has been used by pathologists would seem to imply that they were fully persuaded of its existence and very extensive operation in the animal economy; for there is no explanation of morbid phenomena more familiarly in use with the learned or the unlearned, than that of ascribing them to loss of tone, or the state of atony. And, certainly, no class of remedies enjoys a higher degree of popularity than those which, under the designation of tonics, are supposed to possess the power of restoring or increasing the tone of the several organs of the economy, and particularly of the digestive. In examining these expressions with any degree of accuracy, however, we shall find that all which is in general meant to be implied by the use of the term tone, whether applied to the economy generally, or to particular parts of it, is merely vigour of action, without any consideration being paid to the question, whether this depends on a single and peculiar power, or is the result of the combined operation of several distinct powers.

Even in regard of the voluntary muscles, it may be a matter of no small difficulty to decide, when a particular class of muscles are in a state of preternatural contraction, whether this depends on what we have called *spasmodic* irritable contraction of their own fibres, overcoming the resistance of their antagonists, or on their *tonic* contraction, consequent on a loss of tone on the part of their antagonists. In wry-neck, for example, is the primary affection, so far as the muscles are concerned, in those on the side towards which, or in those on the side from which, the head is turned? or may it in some instances depend on one of these causes, and in other instances upon the other cause, affording what Dr Good has designated the two varieties of loxia *irritata*, or spastic wry-neck, from excess of muscular action on the contracted side; and loxia *atonica*, or atonic wry-neck, from direct atony of the muscles on the yielding side?

In involuntary muscular organs, however, it must be a matter of infinitely greater difficulty to trace the influence of pathological conditions of the property of tonicity, in consequence of the more concealed and more limited field of its operations. One of the pathological phenomena occurring in an organic function which seems most to favour the hypothesis of tonicity as a distinct power from irritability, is the state of the arteries in inflammation. Notwithstanding the increased velocity with which, in some cases at least, the small or capillary arteries of an inflamed part propel their contents, they are in a state of distention. Dr Thomson, in his experiments on the effects produced by applying various substances to the web of the frog's foot, found that the state of the capillary vessels thus excited that bore the greatest resemblance, in outward appearance, to the state of inflammation, was that which occurred on the application of a saturated solution of common salt. In this case, the arteries, instead of being contracted, as he found to happen when ammonia is applied, were actually and sensibly dilated. "The part of the web to which the salt was applied became of a red colour, and this redness, which was visible to the naked eye, lasted in general for a period of from three to five or more minutes. It was impossible to view with the naked eye the part to which the salt had been applied, without conceiving it to be inflamed." As in some cases the application of the salt produced an increased velocity in the circulation through the dilated larger and smaller arteries and capillary vessels to which it was more immediately applied, the vascular distention, obviously, could not be attributable to mechanical obstruction.

Whether the distended state of the capillary arteries in inflammation, a state which, it thus appears, can be so readily imitated, if not induced, by the action of salt upon the web of the frog's foot, be attributable to a loss of tone in their parietes, seems a question fairly open for the consideration of pathologists. The idea seems to receive countenance from an interesting observation of Dr Alison's, who found that when, subsequently to death, an artery going to an inflamed limb is compared with the corresponding artery going to an uninflamed limb, it is of larger calibre, and possesses less power of re-acting upon a distending fluid. (*Edin. Med. and Surg. Journ.* xlv. 98.)

On the whole, it may, we believe, without injustice be affirmed that, to determine the propriety of recognising such a peculiar vital property as tonicity at all, and, in the event of its recognition being found necessary, to ascertain the particular phenomena, physiological and pathological, which ought to be referred to its agency, would require a much more precise method of analytical investigation than has ever yet been brought to bear on the elucidation of this subject.

Sensib

The next vital property which we have to mention as generally recognised by physiologists, is sensibility. As voluntary motion consists of an affection of the mind succeeded by an affection of certain parts of the organic frame, viz. the voluntary muscles; so sensation consists of an affection of certain parts of the organic frame, viz. the organs of sense, succeeded by an affection of the mind. In both cases we have reason to believe that the nerves are the media of communication between the brain as the organ of the mind and the other parts of the body. In speaking of sensibility as a vital property, it is necessary to keep in mind the twofold character of sensation, as a corporeal and as a mental phenomenon. We presume that those agents the application of which to certain parts of the body is ultimately followed by those states of mind which we designate sensations, produce some change in the state of the nervous extremities, and that some corresponding changes subsequently ensue in the nervous cords, and ultimately in the brain; just as we presume that, in voluntary motion, the affection of the mind acts in some way on the brain, and that the change induced in this organ is propagated along the nerves to the muscular fibres.

Although the property of irritability is liable to be called into play in a large class of muscles, by the particular state of mind termed the will or volition, yet, in the assistance which it gives in effecting a number of the functions of the animal economy the mind has no share, these functions being purely corporeal. Different names have been given to the irritability of muscular fibres, according as it is called into operation by one or other of these causes, viz. the will or material stimuli, and amongst these the names of animal and organic contractility. Some physiologists have conceived that a similar distinction may be established in respect of sensibility; that, besides what is called animal sensibility, or that property of the nervous system in virtue of which impressions produced on particular parts of the body by external agents, or by peculiar conditions of its own textures, are communicated through the brain to the mind, there is an organic sensibility, in virtue of which the different textures themselves become sensible of the action upon them of external agents; "la faculté," says M. Cailliot, "qu'ont les parties des corps animés de récevoir des impressions quelconques, qui produisent des changemens proportionnés à ces impressions." So completely independent of mind did Bichat, the great advocate of organic sensibility, consider this property to be, that he ascribes it to vegetables. "Nature," says he, "has endowed each portion of a vegetable with the faculty of feeling the impression of the fluids with which the fibres are in contact." (*Anat. Génér.* i. xli.) But if this application of the term sensibility be legitimate, we do not see how it can be confined to the phenomena of organic beings. A piece of marble may with equal propriety be said to be sensible of the impression of the acid which resolves it into its constituent elements; and a detonating powder sensible of the impression of the blow which occasions its explosion. The word sensibility, which is intended to denote a peculiar form of susceptibility, a form the essential peculiarity of which consists in its terminating in the production of a particular state of mind, would in this way be rendered synonymous with susceptibility in general. It is probable that the idea of an organic sensibility may arise in part from the belief entertained by physiologists, that, in many instances, external agents, in acting upon our corporeal organs, do not act upon them directly, but through the intervention of the nerves, the same channels by which sensible impressions are conveyed to the brain as the organ of the mind. But even this point of analogy, if fully established, would not warrant us in connecting the name of sensibility with a phenomenon with which the mind is in no way related.

It orbid co itions.

In respect of sensibility, we know that, independently of any perceptible alterations in the organization of the several parts concerned in the exercise of that function (from that part upon which the impression is primarily made, to that by which it is transferred as it were to the mind, so as to become an object of consciousness), morbid variations are liable to occur, both as regards the intensity of the sensations produced by a given amount of impression, and as regards the qualities of the sensations. Under a variety of circumstances more or less perfectly understood by us, our sensations (both those depending on the impression of external objects, and those which result from processes going on within the body, or our sensations of impression and of consciousness, according to the distinction recognised by Dr Cullen) are liable to become more intense than they are in the state of health. In other circumstances, these sensations, particularly those of impression, become less distinct than natural, or are not at all produced; a state variously designated by nosologists, according to the seat which it may occupy, but which, from its frequent coincidence with diminished muscular irritability, has often been improperly included under the term of paralysis or palsy.

In xcess.

In efici- en

Pe erted.

The various morbid conditions of sensibility which cannot be referred to the two heads of increased and diminished, and which are therefore included under that of vitiated or perverted, seem referrible to the three following: 1*st*, The perception of objects that do not exist, as when those appearances which have been called *muscæ volitantes* are seen floating in the air like dark or luminous spots, lucid ribbons, &c.; 2*d*, the perception of external objects otherwise than they really are or appear to others, whether as respects their number, form, size, colour, or state of motion or rest; and, 3*d*, the perception of the qualities of bodies different from what is usual to us, as when those substances which in health are agreeable to us, become disagreeable, or the reverse.

When these various conditions of sensibility occur as dynamical affections, it is by no means easy for the pathologist in all instances to ascertain in what portion of the nervous system the dynamical affection has its more immediate seat; whether in the extremities of the nerves on which the impression is first received, or in the nervous cords by which it is conducted to the brain, or in the brain itself, in which we presume that some change must be produced previously to the affection of the mind which completes the function of sensation. When, for example, the sense of sight is lost, as in amaurosis, and no perceptible change of structure can be discovered capable of explaining the morbid phenomenon, are we to seek for the seat of the dynamical affection in the retina, in the optic nerve, or in the part of the cerebral mass with which that nerve is more immediately connected?

Supp ed iden y of irrita lity and s si- bility

Before passing from the consideration of the properties of irritability and sensibility, we may observe, that nothing can mark more strongly the extreme difficulty which exists in obtaining the general recognition of the clearest and best established truths of science, than the frequent proposals that have been made, since the differences in the characters of these two vital, or, more correctly speaking, animal properties, irritability and sensibility, were fully demonstrated by Haller, to re-unite them as one property under a common denomination, such as that of excitability, &c. That there is a coincidence in some of their laws, may be admitted; so is there in some of the laws of heat and light, which, too, frequently occur in combination. But the physiologist has no stronger reason for alleging identity in the one case, than the natural philosopher for alleging it in the other; and nothing, we are persuaded, can be conceived more calculated than this confusion to retard the progress of medical science. It has frequently, indeed, been argued in favour of this identity, that irritability implies sensibility; that everything which is irritable must be sensible, in order that it may perceive the stimulus which calls it into action. But, as has been already shown in speaking of organic sensibility, we might as well say that every thing which is inflammable must be sensible, in order that it may perceive the impression of heat; that gunpowder must be sensible of the spark which inflames it.

Nervous energy.

A strong belief has existed among medical men that the several organs of the body are greatly dependent, for the suitable exercise of their functions, on an influence or energy communicated to them by the different parts of the nervous system; some organs being supposed to be more immediately under the control of its cerebro-spinal, and others under that of its ganglionic portion.

This belief has had its origin in the interruption to the exercise of the different functions which has been found to be occasioned by division of the nerves of their respective organs, or by the removal or destruction of particular portions of the nervous system, as well as in the functional derangements that are observed to occur under the influence of diseases of that system, or under the operation of certain agents, such as opium, upon it.

Mode of operation.

But though the facts that have been alluded to seem to warrant the general inference that the central portions of the nervous system exercise, through the medium of the nervous cords, an important influence on the performance of the several organic functions, as well as of those in which consciousness is involved, it must be confessed that we are still unable, from the results of physiological experiments, numerous as these have been, or of pathological observations, to say in what particular manner this influence is brought to bear upon the organic functions, and in what manner it operates. Those who recognise the operation, in the animal economy, of a peculiar principle, to which, from its source, the name of innervation has been given, are not able to say whether it produces or concurs in producing phenomena of a physical or of a chemical character; whether its mode of operation be the same in all the different functions, as the notion of its being a special agent or principle would lead us to conclude, or peculiar in each. Thus, for example, physiologists have very generally concurred in admitting that an influence derived from the nervous system is essential to the performance of the function of digestion, seeing that the division of the par vagum, or the destruction of particular portions of the brain or spinal marrow, put a stop to its continuance. But there is very far from being a like concurrence of opinion as to the particular process or part in the performance of this function, with which that nervous influence is more immediately connected, and the interruption of which causes the discontinuance of the whole function; whether the nervous influence be essential to the conveyance of blood to those secreting organs by which the fluids of the stomach are elaborated; or whether it assists these secreting organs in the performance of their task; or whether it aids in those reciprocal chemical actions which take place between the gastric fluids and the food introduced into the stomach; or whether, by maintaining the peristaltic motion of the stomach, it contributes to the physical removal of the portion of food that has been acted on by the gastric juices, and to the bringing of a new surface of the food in contact with them; or, lastly, whether it may not be that several or all of these successive phenomena of the function of digestion depend on the influence which the stomach derives from the central portions of the nervous system, the ganglionic as well as the cerebro-spinal, through the nerves which ramify in its parietes.

Supposed identity with galvanism.

At one time there seemed reason to believe that physiologists had ascertained the nature of the influence communicated by the nervous system to the several organs of the body—and were thus put in a fair train for ascertaining its mode of operation. When it was found that the interruption to the process of digestion, occasioned by the division of the par vagum, could be obviated by connecting the lower extremity of the nerve with a galvanic battery, or even by allowing its divided extremities to approach within a small distance of one another, it was scarcely possible to resist the conclusion, that galvanism was the active principle essential to the exercise of digestion, of which the division of its nerves deprived the stomach. More recent observations, however, have suggested doubts as to the correctness of this conclusion, and threaten to deprive us of the simple solution of the problem of innervation which it seemed to afford.

Some physiologists, indeed, doubt altogether the production in the central portion of the nervous system, and propagation along the nervous cords, of an energetic power or principle aiding the several organs in the exercise of their particular functional phenomena; and conceive, that in respect of the organic functions the nervous system acts as a medium of communication between their organs and the stimuli or impressions by which they are called into action. According to this hypothesis the food introduced into the stomach produces a particular impression on the extremities of the gastric nerves, which is propagated along the nervous cords to the nervous centres, and the nervous centres being in some way affected by the impression, react, through the same medium of communication, upon the organs in which a change is to be produced; as, for example, upon those which secrete the gastric fluids, or upon those which effect the peristaltic motion of the stomach. If this can be proved to be the correct explanation of the manner in which the nervous system operates in promoting the performance of the organic functions, it may be right to employ some appropriate term to designate it; but, for the reasons already assigned, we must avoid giving to this intervention of the nerves the denomination of sensibility, even with such a qualifying appellation as *organic*.

Application to pathology.

With the physiological doctrine of innervation in a state of so much embarrassment and uncertainty, it cannot be expected that in pathology it should be possible to make any very precise or extensive application of it to the explanation of morbid phenomena. It is obvious, however, that many of the facts on which the doctrine of innervation rests are of a pathological nature. And it is by availing himself of the experiments which nature as it were performs to his hand,—by noting, in cases of organic diseases of the different portions of the nervous system, the changes which occur in the action of the several organs,—that the pathologist may hope to contribute his share to the elucidation of this difficult subject.

In recognising variations in the condition of this vital power, as a probable source of morbid derangements in the exercise of the functions, the pathologist must be careful not to give to this source of morbid actions an overwhelming preponderance, to the exclusion of variations in the other powers, inorganic or organic, that are concerned in the production of the various phenomena of the animal economy. With some pathologists, dynamical derangement of function and innervatory derangement seem to be regarded as synonymous expressions, as if, whenever an organ, in which no structural alteration is discoverable, performs its function in an irregular manner, this must depend on some disturbance of its innervatory influence. But this is by no means the case. Of the three conditions of the economy, for example, described by M. Andral, in which palpitation of the heart is liable to occur, independently of organic lesion, viz. a state of plethora, a state of anemia, and a state unattended with either of these conditions of the vascular system, it is in the last only, in which we conclude that the nervous centres are themselves affected, that we are entitled to attribute the palpitation of the heart to a *lesion of innervation.*

From the nature of the connection which subsists between the nervous system and the several organs of the body, it follows that a *dynamical* affection of an organ,—that is to say, a morbid exercise of its function, unattended with any perceptible alteration in its own structure,—may depend on an *organic* affection of some distant part of the nervous system; and it is particularly by tracing such dependencies that pathological anatomists have diminished or sought to diminish the number of diseases previously regarded as ultimately dynamical.

Sympat

There is still another form of nervous conduction to which, under the name of sympathy, pathologists frequently refer in their explanations of morbid phenomena, and which, without being in itself a new source of such phenomena, occasionally modifies in a very important manner the relations between proximate causes of disease and the symptoms by which they manifest their existence.

There are, perhaps, few terms under which a greater diversity of phenomena have been sought to be comprehended than that of sympathy, owing in a great measure to the very imperfect analyses with which medical inquirers too frequently content themselves, of the succession of events by which an obvious result is preceded. To us it appears, that in medical language the term sympathy ought strictly to be confined to denote the arising of sensations, motions, or other vital changes, in the animal economy, suddenly and without the intervention of the will, from external or internal impressions made upon, or irritations excited in parts distinct or at a distance from, those in which these sensations, motions, or changes, actually occur; and in pathology more particularly to denote a certain co-suffering or condolence of different parts, in consequence of which, when one part is morbidly affected, either all the other parts of the body, or some particular and different part, is simultaneously affected, either in the same or in some different but obvious manner. When the sympathetic morbid affection extends to all parts of the body, as when the state of fever is produced by a wound, it is said to depend on the general sympathy of the economy. When, again, the sympathetic affection is limited to some particular part, as when the presence of stone in the bladder gives rise to itchiness and pain at the extremity of the urethra, it is said to depend upon a particular sympathy.

The great variety of pathological phenomena which have been regarded as sympathetic, may perhaps be referred to two general classes, sympathetic sensations and sympathetic motions. According to the general definition that has been given of pathological sympathetic phenomena, it obviously follows that sympathetic sensations are those which we experience in a part distinct from that to which the exciting cause is applied; as when the sensation of itchiness of the nose is occasioned in children by the presence of worms in the intestines. Sympathetic motions, in like manner, are those that occur in particular muscles or muscular organs, in consequence of the application of a physical stimulus to a part distinct from that to which they immediately belong, and with which they cannot be shown to have a direct nervous communication; as when cramps occur in different muscles, particularly those of the lower extremities, from the presence of acid or of bile in the alimentary canal; or when disturbance of the action of the heart is produced by the same causes.

In every sympathetic phenomenon, two distinct parts of the body must be considered as being concerned; 1*st*, that on which the primary impression of the external agent is made; and, 2*d*, that in which the sympathetic effect is manifested. In speaking, therefore, of the sympathies of any organ, as the stomach, for example, we may consider it either, 1*st*, as being the part primarily acted on by an external impression; or, 2*d*, as being the seat in which the operation of the external impression becomes apparent to us by the production of the sympathetic effect. It has been to mark this distinction that the terms active and passive sympathies have been employed; an organ being said to have an active sympathy with another organ, when an impression made on the first is followed by a sympathetic affection of the second organ, while, in this case, the second organ is said to have a passive sympathy with the first.

"In endeavouring to discover some general principle or principles capable of accounting for the phenomena of sympathy, medical men have been led to believe that sympathetic connections exist principally between parts bearing a close resemblance to one another in their structure, or having a community of function, and between parts connected with one another by means of vessels and nerves, or situated in the vicinity of one another. Finding that the two former of these circumstances, resemblance of structure and similarity of function, did not lead to any satisfactory explanation of the phenomena of sympathy, attention was more particularly directed to the two last of the circumstances mentioned, especially to the communication existing between parts, whether near to or remote from one another, through the medium of nerves. It was soon observed that there are four ways in which a connection may be established between distinct or distant parts, through the medium of nerves; 1*st*, the same nerve may in its course pass through different parts; 2*d*, a nerve may send branches to different parts; 3*d*, two or more nerves going to different parts may arise from the same portion of the central part of the nervous system,—the brain and spinal marrow; 4*th*, two or more such nerves, though arising from different portions of the common sensory, may be connected with one another in their course by anastomosing branches. These possible different modes of nervous communication suggested to physiologists the further inquiry, whether, when a sensation, motion, or other vital action arises in some part of the body, in consequence of an impression made on some other distinct part, the impression must first be communicated from the part primarily affected, to the brain, and from thence be transmitted to the part in which the resulting sensation or action occurs; or whether the impression may pass directly from the part on which the external agent operates, to the part ultimately sympathetically affected, without passing through the brain."

Vit affinity.

Physiologists are accustomed to assert, with very considerable confidence, that the chemical processes or operations which take place in organized beings are regulated by laws not only different from, but opposed to, those that preside over the chemical changes which occur in inorganic bodies; and that it is consequently necessary to admit the agency, in their production, of a principle different from any recognised in inorganic chemistry. To this principle, when regarded as distinct from the general vital principle of some physiologists, they give the name of vital affinity. The arguments alleged in favour of the existence of such a principle are threefold: *First*, that we are unable to render an explanation of many of the chemical processes occurring in organized bodies; *second*, that in living systems, chemical combinations are effected, or organic compounds are formed, to which nothing analogous is met with in dead matter, and which the chemist is unable to imitate; and, *third*, that elements remain combined in living systems, which, under the ordinary laws of chemical affinity, would speedily separate from one another, so as to produce decomposition of their compound products. Notwithstanding the confidence with which these arguments have been urged, and the assent which they have very generally received, to us, we confess, it appears that if there really exist in living economies any principle or principles capable of producing chemical combinations and decompositions different from those of inorganic chemistry, both its general character, and the particular phenomena which depend upon its agency, remain yet to be discovered.

It is no way impossible that nature may employ in living economies a peculiar principle of chemical action, just as, in the case of irritability at least, she employs in the animal kingdom a peculiar principle of physical action. But, supposing this to be the case, from the harmony which we find to prevail through all parts of nature's works, we may be assured that this chemico-vital principle, if it actually exists, must be supplementary and additional to, and not inconsistent with or subversive of, those other principles which regulate the phenomena of chemical combination and decomposition.

In regard to the first argument which we have mentioned in favour of the existence of a particular principle of vital affinity, it would not, we believe, be difficult to show that our inability to render an explanation of many of the chemical processes that go on in the animal economy, is owing to our ignorance of the phenomena as they actually occur—to our seeing the results only, and not the means by which they are brought about; that, so far as we are acquainted with the chemical phenomena of the animal economy, they do not exhibit anything inconsistent or irreconcileable with the ordinary laws of chemical affinity as manifested in the inorganic world; and that the better we become acquainted with the circumstances under which chemical actions take place in living bodies, the more are we enabled to explain them conformably with these laws.

In regard to the second argument, it might, we conceive, be shown, that it is not universally true that organic compounds cannot be imitated exterior to living economies, as is shown by the preparation of oxalic acid, of sugar, of camphor, of allantoic acid, and of urea, in the laboratory of the chemist; and that even though the chemist were unable to imitate organic chemical products, this would not be a conclusive argument in favour of the existence of a distinct vital chemical principle, unless we could show that the means employed by him in his attempts to effect this were, in every other essential, analogous to those which nature employs in the living economy.

The third argument which we have mentioned, is that upon which the supporters of a principle of vital chemical affinity have most confidently relied. They appeal triumphantly to the changes which an organized body undergoes subsequently to death, as exhibiting the natural tendencies of the elements of which its several parts consist, under the ordinary laws of chemical affinity; and represent the prevention of these during life as the effect and the evidence of a peculiar chemico-vital principle. But it is strange that they should overlook how materially any one portion of an organized body, which they may mark as undergoing putrefaction subsequently to death, is altered in its circumstances from its condition during life, by the cessation of the processes of absorption, nutrition, exhalation, &c. And it is, perhaps, still more strange, that they should think it necessary to invoke a peculiar agent for the explanation of an effect, viz. the prevention of putrefactive decomposition, which, in the casks of the curer, or the jars of the anatomist, they may see effected by products of inorganic chemistry.

On the whole, we conclude, that the physiologist in prosecuting his investigation of the changes of combination and decomposition which occur in the animal economy in the state of health, and the pathologist in endeavouring to ascertain the deviations to which these are subject in the state of disease, are entitled to proceed on the belief, that whatever differences there may be in the resulting products, their formation is regulated by the same laws to which the chemical changes of inorganic substances are subjected; and that where these laws seem inadequate to the explanation of any particular phenomenon, they may be certain that the circumstances of that phenomenon are still imperfectly understood.

Conclusion.

We must here terminate the view which we have attempted to sketch of the vital powers that are concerned, conjointly with the powers common to all forms of matter, in producing the corporeal phenomena of the animal economy, and of the variations to which these powers are liable in the state of disease. Though very imperfect, we trust this view has been sufficient to show how little is as yet actually known of what may be called the mechanism of the functions, or the agencies engaged in the performance of their several parts; and how little, consequently, medical men are prepared to analyse and reduce to their primary elements those deviations from healthy exercise which the different functions experience in the various states of disease, independently of structural alterations. Hence it happens, that the pathologist is frequently compelled to stop short, in framing his proximate causes, at the general functional derangement of which he obtains evidence, instead of attempting to trace this back to the particular dynamical condition or conditions upon which it may depend; to be content with saying of a secretory organ, for example, that its *action* is excessive, deficient, or vitiated, instead of attempting to determine whether it is in its organic or in its inorganic forces, and in which of these respectively, that the primary source of derangement has its seat.

Before concluding, we shall only farther remark, that it is impossible to review the different sensible alterations of structure which have been enumerated in a former part of this article, as constituting the proximate causes of the various forms of organic diseases, without being satisfied that in very few instances are these the *immediate* results of the action of morbific agents on the several parts of the body; and that previous to the occurrence of those changes which render structural proximate causes perceptible to the senses, dynamical or imperceptible changes must have taken place, the nature of which can be for the most part only a matter of inference. The application of a ligature to a limb, or some other impediment to the return of the blood to the heart by the veins, may produce congestion, dropsy, or perhaps hæmorrhage, as its direct effect; but in those cases in which these morbid conditions occur in what is called an active form, their appearance must have been preceded by a dynamical affection of some portion of the circulatory system. Hence the opinion of those who maintain that the first changes towards disease are always dynamical, is correct, provided it be understood that this term signifies merely changes of action, independently of perceptible changes of structure; changes of action which must primarily originate in the injurious operation of morbific agencies on the insensible conditions of the several textures, systems, and organs of the body. (L. L. L. L.)

PATIENCE is that calm and unruffled temper with which a good man bears the evils of life, from a conviction that they are at least permitted, if not sent, by the best of Beings, who makes all things work together for good to those who love and fear him.

PATIENTIA STRAIT, in the Eastern Ocean, is formed by the south end of Gilolo Island, and the southern extremity of Bachian Island.

PATIGUMO, a corruption of the words *pâte de guimauve*, is the name of a sort of paste or cake much used on the Continent as an agreeable and useful remedy for catarrhal defluxions, and supposed by Dr Percival to consist of gum-arabic combined with sugar and the albumen of eggs. It has been said, however, that the powdered substance of the marshmallow is the chief ingredient of the composition.

PATIN, GUY, professor of physic in the Royal College of Paris, was born in the year 1602. He made his way in the world merely by the force of his genius, being at first only corrector of a printing-house. He was a man of great wit and erudition, and spoke with the gravity of a Stoic; but his expressions were nevertheless very satirical, and he hated bigotry, superstition, and knavery. Notwithstanding his sarcastic tendency, however, he was upright and well disposed, an affectionate father and an amiable member of society. He died in the year 1672, and owed his reputation, not to any writings upon physic published in his lifetime, but to his letters, which appeared after his death.

PATIN, *Charles*, son of the preceding, was born in Paris in 1633, and made so surprising progress, that he maintained, in Greek and Latin, theses on all parts of philosophy, in 1647. He studied the law in compliance with the wishes of an uncle, and was admitted as an advocate in the parliament of Paris; but he could not lay aside the study of physic, for which he had always a decided inclination. Having therefore quitted the law, he devoted himself to physic, and after taking his doctor's degree, he applied himself to practice with success. He afterwards travelled into Germany, Holland, England, Switzerland, and Italy. In 1676 he was appointed professor of physic in Padua; and three years afterwards he was created a knight of St Mark. He died in that city in 1694. His works are numerous, and well known to learned physicians.

PATKUL, JOHN REINHOLD, was descended of a noble family in Livonia, a province which then belonged to the crown of Sweden. The Livonians having been stripped of their privileges, and great part of their estates, by Charles XI., Patkul was deputed to prefer their complaint; a duty which he discharged with such eloquence and courage, that the king, laying his hand upon his shoulder, said, "You have spoken for your country as a brave man should, and I esteem you for it." Charles, however, was determined to punish the zeal and honesty which he thought fit to commend; and a few days afterwards he caused Patkul to be declared guilty of high treason, and condemned to death. Patkul, however, found means to escape into Poland, where he continued until the death of Charles. He hoped that his sentence would then have been reversed; but being disappointed in this expectation, he applied to Augustus king of Poland, whom he solicited to attempt the conquest of Livonia. Augustus, acting on this suggestion, possessed himself of Livonia; and afterwards, when Charles XII. entered the province to recover it, Patkul commanded in the Saxon army which opposed that remarkable man. Charles proved victorious; and Patkul some time afterwards entered the service of the Czar, a little before Charles compelled Augustus to abdicate the throne of Poland, and his subjects to elect Stanislaus in his stead. The Czar then sent Patkul, with the title of his ambassador, into Saxony, to induce Augustus to meet him at Grodno, that they might confer upon the state of their affairs. He succeeded, and the proposed conference accordingly took place; but immediately afterwards the Czar left Grodno for Astracan, to quell a rebellion which had broken out there. As soon as the Czar was gone, Augustus ordered Patkul, who was then at Dresden, to be seized as a state criminal. This proceeding surprised all Europe; for Patkul was not only an ambassador, but an ambassador from the only power that could afford him protection. Patkul, it seems, had discovered that the ministers of Augustus were to propose a peace to Charles upon any terms, and had therefore resolved to anticipate them, and procure a separate peace between Charles and the Czar. But his design was discovered; and, in order to prevent its success, Augustus ventured to seize his person, assuring the Czar that he was a traitor, and had betrayed them both.

Augustus was soon afterwards reduced to beg peace from Charles at any price, and the latter granted it upon certain conditions, one of which was, that he should deliver up Patkul. This reduced Augustus to a sad dilemma. The Czar had reclaimed Patkul as his ambassador; and, on the other hand, Charles demanded, with threats, that the prisoner should be put into his hands. Augustus, therefore, contrived an expedient by which he hoped to satisfy both. He sent some guards to deliver Patkul, who was prisoner in the castle of Königstein, to the Swedish troops; but by secret orders privately despatched, he commanded the governor to let him escape. The governor, however, though he received the order in time, disappointed its intention. He knew that Patkul was rich; and having it now in his power to permit him to escape, he demanded a large sum for the favour. Patkul refused to buy that liberty which he made no doubt would be gratuitously restored; and, in the mean time, the Swedish guards arrived with the order for his being delivered up to them. By this party he was carried to the head-quarters of Charles at Albranstadt, where he continued three months, bound to a stake with a heavy chain of iron. He was then conducted to Casimir, where, being ordered to be tried, he was, as a matter of course, found guilty by his judges. After being kept in a state of horrible suspense for several months, he was, on the 30th of September 1707, put to death, with circumstances of atrocious cruelty, having been broken alive on the wheel, and his agony prolonged with unheard-of barbarity.

Charles XII. has been severely censured for not pardoning Patkul, and we are not inclined to vindicate that sovereign. Yet it must be remembered that this unhappy man was guilty of a much greater crime than that which drew upon him the displeasure of Charles XI. He had incited foreign powers to attack his country when under the government of a boy; hoping, as he said himself, that it would in such circumstances become an easy conquest. He was therefore a rebel of the worst kind, and where is the absolute monarch to be found who would readily pardon such rebellion?

PATMOS, a small island of the Grecian Archipelago, celebrated as the place of banishment of the apostle St John, and where also he wrote his Revelations. It is situated a little to the south of Samos, on the coast of Asia Minor, is between thirty and forty miles in circumference, and now scarcely produces subsistence for the support of its scanty population. It is represented as having been more productive about fifty years back, but has been cruelly laid waste by the pirates who infest these seas. It does not now contain more than 300 inhabitants. In the interior are the remains of a monastery, in a strong position, where formerly the natives were accustomed to take refuge and defend themselves against piratical invaders. Long. 26. 40. E. Lat. 37. 30. N.

PATNA, a large and celebrated city of Hindustan, in the province of Bahar, of which it is the capital. It is a city of great antiquity, and is supposed to have been the Palibothra of the ancients. It is situated on the southern shore of the Ganges, which is here five miles wide during the rainy season, and deep enough to float a ship of war. The city is built along the river, and is one continued street for many miles along the Ganges, whilst it is only one mile in breadth. The houses of the natives are generally built of mud; but those of the Europeans, which extend from Bankipoor, are of brick, and make a very handsome appearance, which is not the case with the rest of the city. It contains several mosques and temples; but they are old, and without ornament. It was formerly fortified after the fashion of Hindustan, and still possesses a small citadel, which is now used as a barrack and store-house; but neither this nor the fortifications of the town could have resisted a regular attack of modern artillery for twenty-four hours, although it has often made an obstinate defence against the attack of Indian troops. The town is large and populous; and chintzes and dimities of various kinds are manufactured here, as well as cloths resembling diaper and damask linen. Flannels are also woven in the vicinity, as well as a sort of canvass from cotton. The neighbouring country produces the finest opium and saltpetre, and great quantities of wheat and other valuable grains; also sugar and indigo. Opium and saltpetre are strictly monopolized; but a considerable trade is carried on in all other articles. A large quantity of saltpetre is annually despatched for internal consumption, and for exportation. It was here that the English first established a factory, the remains of which are still to be seen, where two hundred English prisoners were massacred in 1763, under the orders of the German adventurer Somro, or Summers, then in the service of Meer Cossim; immediately after which the city was captured by the British, and has ever since remained in their possession. A monument is erected to the sufferers, in the European burying-ground. The Company have erected here a depôt to contain rice. It is a building of stone, in shape like a bee-hive, with two winding staircases on the outside, which have been ascended on horseback. Bankipoor, one of the suburbs of Patna, is the residence of the servants of the Company. They compose a numerous establishment, with liberal appointments. The travelling distance from Patna to Calcutta by Moorshedabad is 400 miles, from Benares by Buxar 155, from Delhi 661, from Agra 544, from Lucknow 316 miles. Long. 85. 15. E. Lat. 25. 37. N.

PATOMACK. See POTOWMACK.

PATONCE, in *Heraldry*, is a cross, flory at the ends, from which it differs only in this, that the ends, instead of turning down like a fleur-de-lis, are extended somewhat in the pattee form.

PATRAS, a city of Greece, known to the ancients by the name of *Patræ*, and to the Turks by that of *Batra*. It is situated in the gulf of the same name, in a plain which is green, and to appearance well cultivated, and, especially to the northward, has extensive fruitful vineyards. The currants grow most abundantly, and are as fine as those of Zante. Vast quantities of them are annually exported. They are spread in bunches along the ground, and in eight days are sufficiently dried, when the stalks are picked off, and they are laid on the ground in heaps, in the field, ready for the purchasers. The city once contained 12,000 inhabitants, but they suffered much during the hostilities which terminated in their independence. It was the residence of the British consul-general of the Morea, and of agents from most of the European nations. It was formerly celebrated for its fabrics of silk goods, but these have nearly disappeared, and there is scarcely any other manufacture except that of making leather saddle-bags. It has good anchorage, well sheltered, with from three to ten fathoms depth of water. Long. 21. 47. E. Lat. 38. 14. N.

PATREE, a large and populous town of Hindustan, in the province of Gujerat, and capital of a small district. It is defended by three walls, the inner one being surrounded by a good wet ditch, which, even in the dry season, contains a considerable quantity of water. It was formerly considered as a place of great strength, and is often mentioned in the annals of the country. But the fortifications are now in a state of decay, and are in many places falling to pieces. The north face is protected by a beautiful tank, which renders an attack on that quarter entirely impracticable; and the town, on the whole, is still one of the strongest places in India. This place formerly belonged to the rajah of Drangdra, an independent chief of Cottewar; and is now governed by a Hindu chief, who is tributary to the Poonah Mahrattas. Long. 71. 35. E. Lat. 22. 50. N.

PATRIARCH, PATRIARCHA, one of those first fathers who lived towards the beginning of the world, and became famous by their long lines of descendants. Abraham, Isaac, and Jacob, and his twelve sons, are the patriarchs of the Old Testament; Seth, Enoch, and others, were antediluvian patriarchs. The authority of patriarchal government existed in the fathers of families, and their first-born after them, who exercised all kinds of ecclesiastical and civil jurisdiction in their respective households; and to this government, which lasted till the time when the Israelites sojourned in Egypt, some have ascribed an absolute and despotic power, extending even to the punishment of death. In proof of this is produced the curse pronounced by Noah upon Canaan;[1] but it must be observed, that in this affair Noah seems to have acted rather as a prophet than a patriarch. Another instance of supposed despotic power is Abraham's turning Hagar and Ishmael out of his family;[2] but this can hardly be thought to furnish evidence of any singular authority vested in the patriarchs, as such, and peculiar to those early ages. The third instance brought forward to the same purpose is that of Jacob's denouncing a curse upon Simeon and Levi,[3] which is maintained by others to be an instance of prophetic inspiration rather than of patriarchal power. The fourth instance is that of Judah with regard to Tamar,[4] in reference to which it has been remarked, that Jacob, the father of Judah, was still living; that Tamar was not one of his own family; that she had been guilty of adultery, the punishment of which was death by burning; and that Judah on this occasion might speak only as a prosecutor, not as a judge. Upon the whole, however, it is difficult to say which of these opinions is most agreeable to truth. Men who believe that the origin of civil government, and the obligation to obedience, arise from a supposed original contract, either real or implied, will be naturally led to weaken the authority of the patriarchs; and those, again, who consider government as a divine institution, will be as apt to exalt that authority to the highest pitch that either reason or Scripture will permit them. It cannot be denied, that authority existed in fathers, and descended to their first-born, in the primitive ages of the world; and it is neither unnatural nor improbable to imagine, that the idea of hereditary power and hereditary honours was first taken from this circumstance. But whether authority has descended through father and son in this way to our times, is a circumstance that cannot in one instance be asserted, and may be denied in a thousand. The real source of the dignity and of the authority of modern times seems to have been skill in the art of war, and success in the management of conquests.

Jewish PATRIARCH, a dignity, respecting the origin of which there have been a variety of opinions; some thinking it of very ancient institution, whilst others contend that it is not older than the time of Nerva, the successor of Domitian. It seems probable that the patriarchs were of the Aaronic or Levitical race; the tribe of Judah being at that time too much depressed, and too obnoxious to the Romans, to be able to assume any external power. But of whatever tribe they were, their authority came to be very considerable. Their principal business was to instruct the people; and for this purpose they instituted schools in several cities. Having gained great reputation for extraordinary learning, zeal, and piety, they might, in time, not only have brought a great concourse of other Jews from foreign parts, as from Egypt and other western provinces of their dispersion, but likewise have proved the means of their patriarchal authority being acknowledged there. From these they at length ventured to levy a kind of tribute, in order to defray the charges of their dignity, and of the officers under them, whose business it was to carry their orders and decisions through the other provinces of the dispersion, and to see them punctually executed by all, that some shadow of union at least might be kept up amongst the western Jews. They likewise nominated the doctors who were to preside over their schools and academies; and these were in process of time styled *chiefs* and *princes*, in order to raise the credit of their dignity, or to imply the great regard which their disciples were to pay to them. These chiefs became at length rivals of the patriarchs; and some of them possessed both dignities at once, an usurpation which not only caused great confusion, but oftentimes very violent and bloody contests. However, as the Jewish Rabbin have trumped up a much older era for this patriarchal dignity, and have furnished us with a succession of patriarchs down to the fifth century, in which it was abolished, it may not be amiss to give our readers the substance of what they have written on the rise and progress of this order of men; at the same time showing the absurdity and falsehood of the pretended succession to this imaginary dignity.

According to the Rabbin, the first patriarch was Hillel, surnamed the *Babylonian*, because he was sent for from thence to Jerusalem about a hundred years before the ruin of their capital, or thirty years before the birth of Christ, to decide a dispute about the keeping of Easter, which on that day fell upon the Sabbath-day; and it was on account of his wise decision that he was raised to that dignity, which continued in his family till the fifth century. He was likewise looked upon as a second Moses, because, like the Jewish legislator, he lived forty years in obscurity, forty more in great reputation for learning and sanctity, and forty more in possession of this patriarchal dignity. They reckon him little inferior to that lawgiver in other excellencies, as well as in the great authority he gained over the whole Jewish nation. The wonder is, how Herod the Great, who was naturally so jealous, could suffer a stranger to be raised to such a height of power, barely for having decided a dispute which must in all likelihood have been adjudged by others long before that time.

However, Hillel was succeeded by his son Simeon, whom many Christians consider to have been the venerable old person of that name who received the divine infant in his arms. The Jews give him but a very obscure patriarchate, although the authors above quoted make him, also, chief of the Sanhedrim; and Epiphanius says, that the priestly tribe hated him so much for giving testimony to the divine child, that they denied him the rites of common sepulture. But it is hardly credible that St Luke should have so carelessly passed over his twofold dignity, if he had been really possessed of such, and have given him no higher title than that of a just and devout man.

---

[1] Genesis, ix. 25.

[2] Genesis, xxi. 9, &c.

[3] Genesis, xlix. 7.

[4] Genesis, xxxviii. 24.

He was succeeded by Jochonan, not in right of descent, but of his extraordinary merit, which the Rabbin, according to custom, have raised to so surprising a height, that, according to them, if the whole heavens were paper, all the trees in the world pens, and all the men writers, they would not suffice to record all his lessons. He enjoyed his dignity but two years according to some, or five according to others; and was the person who, observing the gates of the temple to open of their own accord, cried out, "O temple, temple, why art thou thus moved? We know that thou art to be destroyed, seeing Zechariah hath foretold it, saying, 'Open thy gates, O Libanus, and let the flames consume thy cedars.'" Upon this he is further reported to have complimented Vespasian, or rather, as some have corrected the story, Titus, with the title of king; assuring him that it was a royal person who was to destroy that edifice, on which account they pretend that the Roman general gave him leave to remove the Sanhedrim to Japhne.

The Jewish writers add, that he likewise erected an academy there, which subsisted until the death of Akiba; that this was likewise the seat of the patriarch, and contained three hundred schools, or classes of scholars. Another he erected at Lydda, not far from Japhne, and where the Christians buried their far-famed St George. He lived an hundred and twenty years, and being asked what he had done to prolong his life, he returned this curious answer: "I never made water nearer a house of prayer than four cubits; I never disguised my name; I have taken care to celebrate all festivals; and my mother has even sold my head ornaments to buy wine enough to make me merry on such days, leaving me at her death three hundred hogsheads of it to sanctify the Sabbath." The doctors who flourished in his time were no less considerable, both for their number and character, particularly the famed Rabbi Chanina, of whom the Bath Col was heard to say, that the world was preserved for the sake of him; and Nicodemus, whom they pretend to have stopped the course of the sun, like another Joshua.

He was succeeded by Gamaliel, a man, according to them, of insufferable pride, and yet of so universal authority over all the Jews, not only in the west, but throughout the whole world, that the very monarchs suffered his laws to be obeyed in their dominions, not one of them offering to obstruct the execution of them. In his days flourished Samuel the Less, who composed a prayer full of the bitterest curses against heretics (meaning the Christians), which are still in use to this day. Gamaliel was no less an enemy to them; and yet both have been challenged, the former as the celebrated master of the great apostle of the Gentiles, the other as his disciple in his unconverted state.

Simeon II., his son and successor, was the first martyr who died during the siege of Jerusalem. The people so regretted his death, that an order was given, instead of ten bumpers of wine, which were usually drank at the funeral of a saint, to drink thirteen at his, on account of his martyrdom. These bumpers were in time multiplied, they tell us, to such shameful height, that the Sanhedrim was forced to make some new regulations for preventing so great an abuse.

These are the patriarchs which, the Rabbin tell us, preceded the destruction of the temple; and we need no farther confutation of this pretended dignity than the silence of the sacred historians, who not only make not the least mention of it, but assure us all along that they were the high priests who presided in the Sanhedrim, and before whom all cases relating to the Jewish religion were brought to be decided. It was the high priest that examined and condemned our Saviour, that condemned St Stephen, that forbade the apostles to preach in Christ's name, and that sat as judge on the great apostle at the head of that supreme court. The same may be urged from Josephus, who must needs have known and mentioned this pretended dignity, if any such had existed; and yet he is so far from taking the least notice of it, that, like the evangelists, he places the pontiffs alone at the head of all the Jewish affairs, and names the high priest Ananus as having had the care and direction of the war against the Romans; an evident proof that there were then no such patriarchs in existence.

To all this let us add, that if there had been any such remarkable succession, the Talmudists would have preserved it to future ages; whereas neither they, nor any of the ancient authors of the Jewish church, make any mention of it, but only some of their doctors, who wrote a considerable time afterwards, writers to whom little credit can be given in points of this nature, especially as there are such insurmountable contradictions amongst them, as no authors, either Jewish or Christian, have, with all their pains, been hitherto able to reconcile.

Upon the whole, it appears that, however much Jewish pride may have prompted them to falsify, and to claim an origin more ancient than it really was, they cannot be traced much farther back than the time of Nerva. Nor have the Jews been faithful in giving an account of the authority of these men. They have indeed exaggerated their power beyond all bounds, in the hope of repelling the arguments of Christians; for their power was far more showy than substantial. In time, however, they certainly imposed upon the people; and what power they did possess in such matters as were connected with religion, they exercised with great rigour. In particular, their pecuniary demands became very exorbitant; and this was the cause of their final suppression in the year 429.

Patriarchs, amongst Christians, are ecclesiastical dignitaries, or bishops, so called from their paternal authority in the church. The power of patriarchs was not the same in all, but differed according to the different customs of countries, or the pleasure of kings and councils. Thus the patriarch of Constantinople grew to be supreme over the patriarchs of Ephesus and Cæsarea, and was called the œcumenical or universal patriarch; and the patriarch of Alexandria had some prerogatives which no other patriarch but himself enjoyed, such as the right of consecrating and approving every single bishop under his jurisdiction.

The patriarchate has ever been esteemed the supreme dignity in the church. The bishop had only under him the territory of the city of which he was bishop; the metropolitan superintended a province, and had for suffragans the bishops of his province; the primate was the chief of what was then called a diocese, and had several metropolitans under him; but the patriarch had under him several dioceses, composing one exarchate, and the primates themselves were under him.

Usher, Pagi, De Marca, and Morinus, attribute the establishment of the grand patriarchates to the apostles themselves, who, according to the description of the world then given by geographers, pitched upon the three principal cities in the three parts of the known world, Rome in Europe, Antioch in Asia, and Alexandria in Africa, and thus formed a trinity of patriarchs. Others maintain that the name patriarch was unknown at the time of the council of Nice; and that for a long time afterwards patriarchs and primates were confounded together, as being all equally chiefs of dioceses, and equally superior to metropolitans, who were only chiefs of provinces. Hence Socrates gives the title patriarch to all the chiefs of dioceses, of whom he reckons ten. Indeed it does not appear that the dignity of patriarch was appropriated to the five grand sees of Rome, Constantinople, Alexandria, Antioch, and Jerusalem, till after the council of Chalcedon in 451; for when the council of Nice regulated the limits and prerogatives of the three patriarchs of Rome, Antioch, and Alexandria, it did not give them the title of patriarchs, though it allowed them pre-eminence and privileges as such; and hence, when the council of Constantinople adjudged the second place to the bishop of Constantinople, who till then was only a suffragan of Heraclea, it said nothing of the patriarchate. Nor is the term *patriarch* found in the decree of the council of Chalcedon, by which the fifth place is assigned to the bishop of Jerusalem; nor did these five patriarchs govern all the churches.

There were, besides, many independent chiefs of dioceses, who, far from owning the jurisdiction of the grand patriarchs, called themselves *patriarchs;* such as that of Aquileia; nor was Carthage ever subject to the patriarch of Alexandria. Mosheim[1] imagines, that those bishops who enjoyed a certain degree of pre-eminence over the rest of their order, were distinguished by the Jewish title of patriarchs in the fourth century. The authority of the patriarchs gradually increased, till about the close of the fifth century, when all affairs of moment within the compass of their patriarchate came before them, either at first hand or by appeals from the metropolitans. The consecrated bishops assembled yearly in council the clergy of their respective districts; pronounced a decisive judgment on those cases where accusations were brought against bishops; and appointed vicars or deputies, clothed with their authority, for the preservation of order and tranquillity in the remoter provinces. In short, nothing was done without consulting them; and their decrees were executed with the same regularity and respect as those of the princes.

It deserves to be remarked, however, that the authority of the patriarchs was not acknowledged throughout all the provinces without exception. Several districts, both in the eastern and the western empire, were exempted from their jurisdiction. The Latin church had no patriarchs till the sixth century; and the churches of Gaul, Britain, and other countries, were never subject to the authority of the patriarch of Rome, whose authority only extended to the nearer provinces. There was no primacy, no exarchate nor patriarchate, owned here; but the bishops, with the metropolitans, governed the church in common. Indeed, after the name of patriarch became frequent in the west, it was attributed to the bishops of Bourges and Lyons; but it was only in the primary signification, namely, as heads of dioceses. Du Cange says, that there were some abbots who bore the title of patriarchs.

PATRIARCHAL Cross, in *Heraldry*, is that where the shaft is twice crossed, the lower arms being longer than the upper ones.

PATRICIAN, a title given, amongst the ancient Romans, to the descendants of the hundred, or, as some will have it, of the two hundred, senators chosen by Romulus, and by him called *patres*, or fathers. Romulus established this order after the example of the Athenians, who were divided into two classes, viz. the ἐυπατριδαι, *patricii*, and δημοτικοι, *populares*. Patricians, therefore, were originally the nobility, in opposition to the plebeians. They were the only persons whom Romulus allowed to aspire to the magistracy; and they exercised all the functions of the priesthood till the year of Rome 495. But the cognizance and character of these ancient families being almost extinguished by a long course of years, and frequent changes in the empire, a new kind of patricians afterwards arose, who had no pretensions from birth, but whose title depended entirely upon the emperor's favour. This new patriciate, Zozimus tells us, was established by Constantine, who conferred the quality upon his counsellors, not because they were descended from the ancient fathers of the senate, but because they were the fathers of the republic or of the empire. This dignity in time became the highest of the empire. Justinian calls it *summa dignitas.* In effect, the patricians seem to have had the precedence of the *consulares*, and to have taken precedence of them in the senate; though Faber asserts the contrary. What confounds the question is, that the two dignities often met in the same person; because the patriciate was only conferred upon those who had gone through the first offices of the empire, or had been consuls. Pope Adrian made Charlemagne assume the title of patrician before taking that of emperor; and other popes have given the title to other kings and princes by reason of its eminence.

PATRICIANS, in ecclesiastical writers, were ancient sectaries, who disturbed the peace of the church in the beginning of the third century, and who were so called from their founder *Patricius*, preceptor of a Marcionite called Symmachus. His distinguishing tenet was, that the substance of the flesh is not the work of God, but that of the devil; and on this account his adherents bore an implacable hatred to their own flesh, which they sometimes carried so far as to kill themselves. They were also called *Tatianites*, and formed a branch of the *Encratitæ.*

PATRICK, St, the apostle of Ireland, and the second bishop of that country. He was born on the 5th of April 373, of a good family, at Kirkpatrick, near Dumbarton, in what is now called Scotland, but was then comprehended under the general denomination of Britain. His baptismal name signified, in the British language, valiant in war. During some inroad of certain exiles from Ireland, he was taken prisoner, and carried into that kingdom, where he continued six years in the service of Milcho, who had bought him of three different persons, whence Patrick acquired the name of *Cothraig*, or *Ceathar-Tigh*, that is, *four families.* Here he made himself master of the Irish language, and at last, having effected his escape, returned home on board a ship. About two years afterwards, he formed the design of converting the Irish; and, the better to qualify himself for this undertaking, he travelled on the Continent, where he continued thirty-five years, pursuing his studies under the direction of his mother's uncle, St Martin, bishop of Tours, who ordained him deacon, and afterwards under St German, bishop of Auxerre, who ordained him priest, and gave him his third name of Mawn or Maginim.

An ancient author, Henricus Antisioderensis, who wrote a book concerning the miracles of St German, considers it as the highest honour of that prelate to have been the instructor of St Patrick. "As the glory of a father shines in the government of his sons," says he, "out of the many disciples in religion who are reported to have been his sons in Christ, suffice it briefly to mention one by far the most famous, as the series of his actions shows, Patrick the particular apostle of Ireland, who being under his holy discipline eighteen years, derived no little knowledge in the inspired writings from such a source. The most godly divine pontiff, considering him alike distinguished in religion, eminent for virtue, and stedfast in doctrine; and thinking it absurd to let one of the best labourers remain inactive in the Lord's vineyard, recommended him to Pope Celestine, by his presbyter Segetius, who was to carry to the apostolic see a testimonial of the ecclesiastical merit of this excellent man. Approved by his judgment, supported by his authority, and confirmed by his blessing, he set out for Ireland; and being peculiarly destined to that people as their apostle, instructed them at that time by his doctrine and miracles; and now does and will for ever display the wonderful power of his apostleship." Lastly, Pope Celestine consecrated him bishop, at the same time giving him his most familiar name of ***Patricius***, expressive of his honourable descent, and to impart lustre and dignity to the commission which he now charged him withal for converting the Irish. Palladius had been there a year before him upon the same errand, but with little success; and the saints Kieran, Ailbe, Declan, and Ibar, were precursors both of Palladius and of Patrick. But the great office of apostle of Ireland was reserved for our prelate, who landed in the country of the Evolein, or at Wicklow, in the year 431. His first convert was Sinell, eighth in descent from Cormac king of Leinster; but not meeting with encouragement, he proceeded to Dublin, and thence to Ulster, where he founded a church, afterwards the famous abbey of Saul, in the county of Down. After labouring seven years indefatigably in this great work, he returned to Britain, which he delivered from the heresies of Pelagius and Arius; he then engaged several eminent persons to assist him, and visited the Isle of Man, which he converted in 440, when the bishopric was founded; in the year 448, he returned to the see of Armagh, which he had founded three years before; and in thirteen years more completed the conversion of the whole island. After giving an account of his commission at Rome, he once more returned to Ireland, and spent the remainder of his life between the monasteries of Armagh and Saul, superintending and enforcing the great plan of doctrine and discipline which he had established. After having established schools, and an academy, he closed his life and ministry at Saul Abbey, in the 120th year of his age, on the 17th of March 493, and was buried at Down, in the same grave with St Bridget, and St Columba the apostle of the Picts. Respecting his burial-place, however, there have been great disputes; and it has been a subject of as much debate with the religious, as Homer's birth-place formerly was amongst the cities of Greece. Those of Down lay claim to it, upon the authority of the following verses:

---

[1] Ecclesiastical History, vol. i. p. 284.

These three in Down lie in tomb one,
Bridget, Patricius, and Columba pious.

Those of Glastonbury, in England, found on the old monuments of their church; and some Scotch writers affirm that he was both born and buried at Glasgow. His genuine works were collected and printed by Sir James Ware, 1656. His immediate successor in his see was St Binen or Begnus.

Order of St Patrick, an institution which was founded in Ireland in the year 1783. On the 5th of February in that year, the king ordered letters patent to be passed under the great seal of the kingdom of Ireland, for creating a society or brotherhood, to be called "knights of the illustrious order of St Patrick," of which his majesty, his heirs and successors, were to be sovereigns, and his majesty's lieutenant-general and general governor of Ireland for the time being to officiate as grand master; and also for appointing Prince Edward, and several of the prime nobility of Ireland, knights companions of the said illustrious order.

PATRICK, *Simon*, a learned English bishop, was born at Gainsborough in Lincolnshire in 1626. In 1644 he was admitted into Queen's College, Cambridge, and entered into holy orders. After being for some time chaplain to Sir Walter St John, and vicar of the church at Battersea in Surrey, he was preferred to the rectory of St Paul's, Covent Garden, London, where he continued all the time of the plague in 1665 amongst his parishioners. In 1668 he published his Friendly Debate between a Conformist and a Nonconformist. This was answered by the Dissenters, whom he had much exasperated; but by his moderation and candour towards them afterwards they were perfectly reconciled to him, and he brought over many of them to the communion of the Established Church. In 1678 he was made dean of Peterborough, where he was much beloved. In 1682, Dr Lewis de Moulin, who had been professor of history at Oxford, and had written many very bitter books against the Church of England, sent for Dr Patrick upon his sick bed, and made a solemn declaration of his regret on that account, which he signed, and it was published after his death. During the reign of King James, the dean's behaviour showed that he had nothing more at heart than the Protestant religion, for which indeed he ventured all that was dear to him, by preaching and writing against the errors of the Church of Rome. In 1687 he published a prayer composed for that difficult time, when persecution was expected by all who stood firm to their religion. The year after the Revolution, the dean was appointed Bishop of Chichester, and was employed with others of the new bishops to settle the affairs of the Church in Ireland. In 1691 he was translated to the see of Ely, in the room of the deprived Bishop Turner. He died in 1707, after having published various works, amongst which are his Paraphrases and Commentaries on the Holy Scriptures, in three vols. folio, which, with Lowth on the Proverbs, Arnold on the Apocrypha, and Whitby on the New Testament, form a regular and continued commentary in English on all the sacred books.

PATRIMONY, a right or estate inherited by a person from his ancestors. The term *patrimony* has also been applied to church estates or revenues; in which sense authors still say, the patrimony of the church of St Rimini, Milan, and so on. The Church of Rome has patrimonies in France, Africa, Sicily, and many other countries. To create the greater respect for the estates belonging to the church, it was usual to give their patrimonies the names of the saints who were held in the highest veneration. Thus the estate of the church of Ravenna was called the *patrimony of St Apollinarius;* that of Milan, the *patrimony of St Ambrose;* and the estates of the Roman Church were called the *patrimony of St Peter in Abbruzzo*, the *patrimony of St Peter in Sicily*, and the like.

PATRINGTON, a town of the east riding of Yorkshire, in the wapentake of Holderness, 109 miles from London. It is situated on the river Humber, which is navigable beyond it, but does not now admit such large vessels as formerly. There is a good market, which is held on Saturday. The population amounted in 1801 to 894, in 1811 to 1016, in 1821 to 1244, and in 1831 to 1298.

PATRIOTISM is a love of one's country, one of the noblest passions that can warm and animate the human breast. "Zeal for the public good," says Mr Addison, "is the characteristic of a man of honour and a gentleman, and must take place of pleasures, profits, and all other private gratifications:" "whosoever wants this motive, is an open enemy, or an inglorious neuter, to mankind, in proportion to the misapplied advantages with which nature and fortune have blessed him." This love of our country does not import an attachment to any particular soil, climate, or spot of earth, where perhaps we first drew our breath, though those natural ideas are often associated with the moral ones, and, like external signs or symbols, help to ascertain and bind them; but it imports an affection to that moral system or community which is governed by the same laws and magistrates, and the several parts of which are variously connected one with the other, and all united upon the basis of a common interest. Wherever this love of our country prevails in its genuine vigour and extent, it swallows up all sordid and selfish regards; it conquers the love of ease, power, pleasure, and wealth; nay, when the partialities of friendship, gratitude, private affection, or regards to a family, come in competition with it, it teaches us to sacrifice all, in order to maintain the rights and promote and defend the honour and happiness of our country.

PATRIPASSIANS, Patripassiani, in *Ecclesiastical History*, a Christian sect, who appeared about the latter end of the second century, and were so called from their ascribing the passion to the Father. They asserted the unity of God in such a manner as to destroy all distinctions of persons, and to make the Father and Son precisely the same; and in this they were followed by the Sabellians and others. The author and head of the Patripassians was Praxeas, a philosopher of Phrygia, in Asia. Swedenborg and his followers seem to hold the same faith.

PATROCLUS, a Grecian chief at the Trojan war. He was the son of Menœtius, by Sthenele, whom some call Philomela or Polymela. The accidental murder of Clysonymus, the son of Amphidamas, in the time of his youth, forced him to fly from Opus, where his father reigned. Having gone to the court of Peleus, king of Phthia, he was cordially received, and contracted the most intimate friendship with Achilles, the king's son. When the Greeks proceeded to the Trojan war, Patroclus went with them at the express desire of his father, who had visited the court of Peleus; and he accordingly embarked with ten ships from Phthia. He was the constant companion of Achilles, lodging with him in the same tent; and when the hero refused to appear in the field of battle, because he had been offended by Agamemnon, Patroclus imitated his example, and by his absence became the cause of much evil to the Greeks. At last, however, Nestor prevailed upon him to return to the war, and Achilles permitted him to appear in his armour. The bravery of Patroclus, together with the terror which the sight of the arms of Achilles inspired, soon routed the victorious armies of the Trojans, and obliged them to fly for safety to the city. He would have broken down the walls; but Apollo, who interested himself for the Trojans, opposed him; and Hector, at the instigation of that god, dismounted from his chariot to attack him as he attempted to strip one of the Trojans whom he had slain. The engagement was obstinate; but Patroclus was at length overpowered by the valour of Hector and the interposition of Apollo. His arms became the property of the conqueror; and Hector would have severed his head from his body had not Ajax and Menelaus prevented it. His body was at last recovered, and carried to the Grecian camp, where Achilles received it with the loudest lamentations. His funeral was observed with the greatest solemnity. Achilles sacrificed near the burning pile twelve young Trojans, four of his horses, and two of his dogs; and the whole was concluded by the exhibition of funereal games, in which the conquerors were liberally rewarded by Achilles. The death of Patroclus, as described by Homer, gave rise to new events. Achilles forgot his resentment against Agamemnon, and entered the field to avenge the death of his friend; and his anger was gratified only by the slaughter of Hector, who had more powerfully kindled his wrath by appearing at the head of the Trojan armies in the armour which had been taken from the body of Patroclus. The patronymic of Actorides is often applied to Patroclus, because Actor was father to Menœtius.

PATROL, in war, a round or march made by the guards or watch in the night time, to observe what passes in the streets, and to secure the peace and tranquillity of a city or camp. The patrol generally consists of a body of five or six men, detached from a body on guard, and commanded by a serjeant.

PATRON, amongst the Romans, was an appellation given to a master who had freed his slave. As soon as the relation of master expired, that of patron began. For the Romans, in giving their slaves their freedom, did not despoil themselves of all rights and privileges in them; the law still subjected them to considerable services and duties towards their patrons, the neglect of which was very severely punished.

Patron was also a name which the people of Rome gave to some great man, under whose protection they usually placed themselves, paying him all kinds of honour and respect, and denominating themselves his clients; whilst the patron, on his side, granted them his credit and protection. They were therefore mutually attached and mutually obliged to each other; and by this means, in consequence of reciprocal ties, all those seditions, jealousies, and animosities, which are sometimes the effect of a difference of rank, were prudently avoided. For it was the duty of the patron to advise his clients in points of law, to manage their suits, to take care of them as of his own children, and secure their peace and happiness. The clients were to assist their patrons with money on several occasions; to ransom them or their children when taken in war; to contribute to the portions of their daughters; and to defray, in part, the charges of their public employments. They were never to accuse each other, or take contrary sides; and if either of them was convicted of having violated this law, the crime was equal to that of treason, and any one was allowed to kill the offender with impunity. This patronage was a tie as effectual as any consanguinity or alliance, and had a wonderful effect towards maintaining union and concord amongst the people for the space of six hundred years, during which time we find no dissensions or jealousies between the patrons and their clients, even in the times of the republic, when the populace frequently mutinied against those who were most powerful in the city.

Patron, in the Church of Rome, a saint whose name a person bears, or under whose protection he is placed, and whom he takes particular care to invoke; or a saint in whose name a church or order is founded.

PATRONAGE is a real or heritable right, of a peculiar nature, connected with ecclesiastical benefices, and of which the main privilege is that of presenting a person to the bishop, presbytery, or other competent ecclesiastical functionaries, in order to his being admitted, according to the rules of the church, to the ecclesiastical office to which the benefice is attached, and of being thereby inducted into the possession of the benefice. This right had its origin in the choice by particular churches, or the appointment by the prince on their application, of defenders of their rights and patrimony. These were at first chosen from scholastics or lawyers, and afterwards from nobles and men of arms, and were termed *patroni, defensores, et advocati ecclesiæ*, from which last title comes the name *jus advocationis* or advowson, still applied to the right. Originally the privilege of presenting formed no part of the right of the patrons, who were chiefly guardians of the property of the church, with a certain interest in the funds, termed *patronagium*. In time, founders of churches, or those who acquired right to be so considered by adding to the building or to the endowment, came to be regarded as patrons; and the fourth council of Toledo, in the seventh century, gave to the descendants of founders a right to see that the incumbents did not embezzle or alienate the funds, to which the ninth council (691) added the right of nominating the successor, confining this privilege, however, to the original founder himself, without extending it to his heirs. The office of patron soon became hereditary, but it would appear, from the Novels of Justinian, that in his time the right of presentation was only allowed to the descendants of founders in the case of oratories or private chapels (*Nov.* 123, c. 18), the privilege in regard to churches being apparently confined to the original founder (*Nov.* 57, c. 2). Subsequently, however, the right of presenting was allowed to descendants in regard to churches also, which gradually became almost universally patronate; and ultimately a rule was introduced into the canon law, that where no right of patronage could be shown to exist, the benefice was to be deemed subject to that of the pope as universal patron. The general character of the right of patronage was the same in all the kingdoms where the canon law was received; and although some partial modifications may have been admitted since the Reformation in particular countries, its principal features remain unchanged. We shall content ourselves with a sketch of it as it exists in the northern portion of this island, which presents some peculiarities not unattended with interest.

In Scotland, as in the other countries of Christendom, the system of patronage, as it existed under the canon law, became universally prevalent; but it is not thought to have been introduced earlier than the tenth century. Before the Reformation, however, a very great change had taken place in the condition of the parochial benefices. A large proportion of these were from time to time annexed or appropriated, by grant of the patrons, to bishoprics, abbacies, priories, and other religious establishments. The benefices thus appropriated were termed patrimonial, and were no longer the subjects of the right of patronage. Such benefices were permanently filled by the bishops or religious houses, who drew the tithes as titular rectors, whilst the cures were served either by a member of the religious community to which the benefice was annexed, or by a chaplain or curate having a salary paid him for his services, or at times by a proper vicar drawing vicarage tithe, though in many cases the vicarages also became appropriated as well as the parsonages. A check was attempted to be opposed to this practice of annexation by a statute in the reign of James III. (1471, c. 43); but so general had it been, that at the period of the Reformation there were in Scotland only 262 non-appropriated parochial benefices out of the whole number, consisting of about 940. These 262 were of course the only patronate parochial benefices, and they were partly of laic patronage and partly subject to that of bishops or other ecclesiastics. On the Reformation, the benefices were generally retained by the Roman Catholic incumbents; and in regard to abbacies and other prelacies (as the greater benefices were termed), these were assumed to have fallen to the crown on the abolition of the religious bodies to which they belonged, and were gradually gifted by the crown, first by temporary titles, and ultimately by permanent grant and erection into temporal lordships, to the nobles and persons of influence about the court. The annexed churches of these prelacies were in general totally unprovided for, the obligation to maintain a stipendiary substitute, incumbent upon the religious establishment to which the benefice was attached, not being fulfilled by the new lay proprietors. To provide a maintenance to the ministers serving the cures of these churches, which constituted the greater proportion of the whole parochial churches, the third of the rents of all benefices, including abbacies and other prelacies, was directed to be levied, to form a fund, out of which special grants might be made to such ministers; but this fund of "thirds" was so misapplied, that in reality the ministers were for many years dependent mainly on the voluntary contributions of their congregations, or of individual proprietors in their parishes. For a considerable period these stipendiary cures remained free from patronage; but James VI., notwithstanding the remonstrances of the church, gradually erected them into benefices, subject to the patronage of the respective lords of erection, though, as Sir George Mackenzie, a high prerogative lawyer of the reign of Charles II., observes, "nothing could be so unjust or illegal as these patronages were."

In the meanwhile, as far as regarded the patronate parochial benefices, it had been enacted by a statute, passed in 1567, alongst with a series of acts abolishing Popery and recognising the reformed church, that, whilst the examination and admission of ministers were declared to be in the kirk, the presentation of *laic* patronages should be reserved to the just and ancient patrons. There was no reservation of *ecclesiastic* patronages, and the lay patron was required, within six months after he should come to the knowledge of the vacancy, to present a qualified person to the superintendent or others having commission of the kirk (who then executed the functions subsequently devolved upon presbyteries), otherwise the right of presenting was to fall to the kirk. It was further provided, that if the superintendent refused to admit the person presented by the patron, the latter might appeal to the superintendent and ministers of the province, in other words, to the provincial synod, and from them to the General Assembly, "by whom," the act bears, "the cause being decided, shall take end as they decern and declare." Small as was the number of unappropriated parochial benefices or parsonages to which ministers might be appointed as rectors, these were, in a great many instances, conferred upon persons not in the function of the ministry at all; and, even in 1592, it is set forth in a statute of that year, that these benefices had been generally "disponed to bairns and other persons altogether unable for the said office and function." To remedy this evil, all gifts of such benefices "to sik persons as are not in the function of the ministry, or able to discharge the duty thereof," are by the act declared to be null, with an exception as to those conferred on senators of the College of Justice (the judges of the supreme civil court); and by another statute of the same year, establishing the presbyterian form of church government as it at present exists, presentations were appointed to be directed to presbyteries, which had been generally erected in 1581, with power to them to give collation; but providing always, that they should be bound to receive and admit whatever "qualified minister" should be presented by the king or laic patrons. The same act provided that a previous statute of 1584, declaring the king's supremacy over all estates, as well "spiritual as temporal," and that he and his councils were judges competent over all persons spiritual or temporal, and in "all causes," should in no way be prejudicial "to the privilege that God has given to the spiritual office-bearers of the kirk," in regard, amongst other matters, to the "collation and deprivation of ministers." In 1612 presbytery was abolished, episcopal government restored, and the king's supremacy in all matters spiritual or temporal again unqualifiedly declared; and at the same time it was provided, that if the bishop, to whom presentations were now to be directed, should refuse to admit a "qualified minister" presented by the lawful patron, not only might the patron retain the fruits of the benefice in his own hands, but letters of horning might be obtained to compel the bishop, by the usual executorials of the law, "to do his duty" in admitting the person presented. The remedy thus provided applied only to the case of presentees who had been already admitted to the function of the ministry, as appears also to have been the intent of the provision as to the corresponding obligation on presbyteries to receive presentees, contained in the act 1592, and the privilege of retaining the stipend, provided also for the case of the presbytery's refusal to admit a qualified "minister," in another act of the same year, which is generally viewed as merely an additional clause of that termed the charter of presbytery; so that there does not appear to have been any remedy for refusal to admit a presentee not already in orders, nor any compulsitor to compel even the bishops (who were subject to legal diligence to enforce admission of a party ordained) to grant ordination.

In 1638 presbytery was restored, and the king's supremacy in matters spiritual disclaimed; and in 1642 his majesty agreed, that as to all crown patronages, he would present one out of a list or leet, to be furnished by the presbytery, and which they were to make up with the advice and consent of the greater part of the parishioners. The practical result of this method was, that in all parishes subject to the patronage of the crown, the particular individual for whom the parish declared a preference generally obtained the presentation; and in 1649 patronage was altogether abolished by an act of the estates of parliament. By this statute it was declared, that "whosoever should, upon the suit and calling of the congregation, after due examination of their literature and conversation, be admitted by any presbytery unto the exercise and function of the ministry in any parish within this kingdom," should, without any presentation, but simply "by virtue of their admission," be entitled to the stipend, manse, and glebe; and in order that the proper interests of congregations and presbyteries, and what should be accounted the congregation having such interest, might be determined, it was recommended to the General Assembly "clearly to determine the same, and to condescend upon a certain standing way for being a rule therein for all time coming." The General Assembly accordingly established a directory, which in substance provided that the session of the congregation were to elect a person, whom they were to nominate to the congregation; that if the people acquiesced and consented, the matter was to be reported to the presbytery, who were to take the party chosen on trials, and, if found qualified, to admit him; that if the major part of the congregation dissented, the matter should in like manner be reported to the presbytery, who were to order a new election, unless they found the dissent to be founded on "causeless prejudices;" but that if only a minority dissented, the presbytery were, notwithstanding, to proceed to the trials and settlement, unless relevant exceptions were verified to them. Under this arrangement matters continued till the Restoration, when episcopacy, the king's supremacy in matters spiritual, and absolute patronage, were re-established. These, again, were all done away at the Revolution, when the presbyterian church government was restored, and the matter of the appointment of ministers placed on a totally new footing. By the act 1690, c. 23, patrons were deprived of the right of presentation, in consideration of a sum of six hundred merks Scots (L.33. 6s. 8d. sterling), and of a right to all tithes in the parishes of which they were patrons, to which no one else could show a title. The six hundred merks were to be paid by the heritors of the parish, who were entitled to consign the money, and compel the patron to execute a formal renunciation; whilst the patron, on the other hand, had efficient remedies afforded him for enforcing payment of the compensation. The patron's right to present, however, ceased from the date of the act, and the privilege became competent to the new parties who were now to be intrusted with it, whether the compensation was paid or not. These consisted of the heritors of the parish, being Protestants, and the elders, who were jointly to propose a person to the congregation, "to be either approven or disapproven by them;" and if the congregation disapproved, the disapprovers were to give in their reasons to the presbytery, by whose judgment the "calling and entry" of the minister was to be determined. Under this statute only three or four parishes paid the compensation money, and obtained renunciations from the patrons. The heritors and elders being in possession of their privilege without payment, and not anticipating the repeal of a statute considered as an essential part of the Revolution settlement, naturally did not press payment of the sum, small though it was; whilst the patrons, entertaining the hope of at some favourable opportunity recovering their power, of course refrained from compelling payment, and granting renunciations, and thereby, for a consideration so trifling, cutting off that hope. The expectations of the patrons proved just, and in 1711, the 10th of Queen Anne, restoring their former rights, was passed. This measure, which originated with the opponents of the protestant succession, was hurried through the House of Commons before the members of the church were aware of it. A deputation was, however, immediately despatched by the commission of Assembly, who presented a remonstrance to the House of Lords, and offered every opposition in their power, but unsuccessfully; and no subsequent efforts to obtain its repeal, which were repeatedly renewed by the church, were of any avail. The assembly for many years inserted in their instructions to their commission an injunction to seize any favourable opportunity of applying to parliament for a repeal of this statute; but in 1784, the practice of inserting such injunction was discontinued, the majority of the clergy, now for a long period introduced by means of patronage, having become favourable to its subsistence; and the right still continues to rest upon the footing on which it was placed by the 10th of Queen Anne. By that statute, patrons, with the exception of the few cases where the six hundred merks had been paid, and renunciations obtained, had their former privileges restored, whilst they were also allowed to retain the rights to tithes granted them by the act 1690, as part of the compensation for the privilege then taken from them; and the sovereign, in addition to the proper crown patronages, acquired right to all those which had belonged to the bishops and archbishops, having previously at the Revolution, without any statutory authority, assumed possession, *jure coronæ*, of all the tithes and property belonging to these dignitaries.

The right of patronage, as now existing, is an heritable right, which may be feudalized, and it may be united to and pass along with lands; whilst in regard to all patronages to which no legal title can be shown, the king is held to be patron, being deemed by lawyers to have succeeded in that privilege to the pope. The patron is allowed six months after each vacancy to present; and the period, by the 10th of Queen Anne, runs, not from the time when he may come to the knowledge of the vacancy, as under the act 1567, but from the date of the vacancy itself. If the patron "neglect or refuse" to present within the six months, the presbytery of the bounds become entitled to exercise the privilege *jure devoluto;* but if he have executed a presentation, and taken all requisite steps for having it lodged with the moderator or clerk of presbytery within the proper time, he will not be held to have "neglected or refused," so as to admit the *jus devolutum,* although, from causes over which he has no control, the presentation may not actually have been so lodged; as, for instance, if the patron of a church in Orkney, residing in Edinburgh, should execute and despatch a presentation in amply sufficient time to reach its destination under ordinary circumstances, but it should not arrive in consequence of an unusual prevalence of storms till the six months have expired. Where a presentee has been rejected by a presbytery as disqualified, or on other legal ground, the patron is allowed as long a period to present a second time, as remained unexpired of the six months when his first presentation was lodged. If, however, he have presented a minister already holding a cure, or a party who will not take the oaths to government, or one who shall not within the six months accept or declare his willingness to accept, his presentation of such a party will not stop the currency of the six months;

but if the presentation shall through any cause become ineffectual, and the six months have expired, the *jus devolutum* will take effect, as if no presentation had been offered. This provision was introduced by the 5th Geo. I. c. 29, mainly for the purpose of preventing patrons from keeping benefices vacant by the presentation of parties who either were disqualified, or would not accept, or whose acceptance was dependent, as in the case of ministers already settled, on the will of the church courts. Although, usually, there is only room for the exercise of the patron's right when a vacancy occurs, the law, in special circumstances (where the presbytery are satisfied of the necessity of the proceeding, from the age or permanent illness of the incumbent), sanctions a presentation during his life to an assistant and successor, who, on being admitted and ordained by the presbytery, immediately becomes colleague in the pastoral charge, though he cannot enter into possession of any of the rights of the benefice till the death of the incumbent. In such cases a provision is always required by the presbytery to be made for the assistant and successor, either by the incumbent, or by obligation on the part of the parishioners, or certain of their number. The patron, before presenting, must take the usual oaths to government for persons in public trust; and if suspected of Popery he may be required to purge himself, by signing a special formula framed for that purpose. Any patron refusing to take the oaths, or to subscribe this formula, when required, forfeits his right of presenting for that time to the crown; and in the event of failure by the crown to present within six months, the *jus devolutum* accresces to the presbytery. Whether this disability can be evaded by the disqualified patron nominating a commissioner who can take the oaths, &c. seems not to be determined.

Originally there was no restriction on the patron's choice in regard to the persons from among whom he might select his presentee, provided always that on trial the presentee should be found qualified. By a series of legislative enactments, however, on the part of the church, a special class of persons has been constituted, from among whom alone (or ordained ministers previously taken from the same class) the patron must select his presentee. These are denominated expectants or probationers, or more generally, at the present day, licentitaes. They are required to go through a preparatory train of study, including a full university course of philosophy, and a course of theology, consisting of four years regular or six years irregular attendance on the professors of theology, in one or other of the universities. They are then taken on trials by the presbytery, that judicatory having previously satisfied themselves that the candidate is of "good report, sound in his principles, pious, sober, grave, and prudent in his behaviour; of a peaceable disposition, and well affected to the happy constitution established in this kingdom, both in church and state." The trials consist of examination into the candidate's knowledge of the Latin, Greek, and Hebrew languages, philosophy, theology, and church history, and the delivery of an exegesis in Latin on some controverted head of divinity, and three discourses in English, on which he may also be specially examined. If the presbytery be satisfied, and the candidate subscribe a formula acknowledging the Confession of Faith, and the presbyterian order of church government, and promising to submit himself to the judicatories of the church, they enrol him as a probationer, and grant him a license to preach the gospel. Though the party thus licensed possesses the privilege of preaching, and of leading in public worship, he holds no office in the church, he cannot administer the sacraments or marry, and is only considered as a recognised candidate on probation for the office of the ministry.

When a presentation in favour of a party qualified to accept of it in manner above mentioned, accompanied with his letter of acceptance, and certificate of his, and also of the patron's, having taken the oaths to government, is lodged with the presbytery, if there be any legal objections to it, or if another party dispute the right of presentation, the presbytery generally delay procedure till the question raised be disposed of by the civil courts; but if there be no legal objection, and no competition, they usually pronounce a deliverance sustaining the presentation (though in certain presbyteries no special deliverance is ever pronounced on the presentation), and proceed with the steps towards forming the pastoral relationship between the presentee and congregation, admitting him to the benefice, and ordaining him to the office of the ministry, if not already an ordained minister. The first step is to appoint the presentee to preach to the congregation one or more times as the presbytery may see fit, and to fix thereafter a day for moderating in a call, as it is technically termed, in his favour; that is to say, appointing the presbytery to meet at the parish church on a particular day, or commissioning one of their number to attend on that day, to moderate in or preside over a meeting of the congregation, summoned for the purpose of giving a call to the presentee to be their pastor. On this occasion, after public worship, and a sermon by the minister appointed to preside, the heritors, elders, and parishioners present are invited to subscribe a written call, addressed to the presentee, which, after setting forth that the parties subscribing are destitute of a pastor, and have sufficient assurance of his piety, literature, abilities, and suitableness to their capacities, proceeds thus: "We heartily invite, call, and entreat you to undertake the office of a pastor among us, and the charge of our souls, promising you, upon your accepting this our call, all dutiful respect, encouragement, and obedience in the Lord." The call being subscribed by as many as incline, the presbytery take it into consideration; and before proceeding to the trial of the qualifications of the presentee, they uniformly pronounce a deliverance, sustaining or concurring with the call. As this proceeding presents a marked peculiarity unknown in England, and as the question in regard to the competency of the church courts refusing to settle a presentee in respect of the absence of what they may consider a sufficient number of signatures to the call, or of the positive dissent from it by a majority of the congregation, or of the male heads of families in communion with the church, has given rise to keen discussion and most important consequences to the welfare of the church in past times, and has again become the subject of most anxious consideration, in a form which seems likely to lead to momentous results as regards the interests of the Church of Scotland, a short notice of its origin and history will probably be interesting and useful.

The Scottish reformers, in framing their scheme of church polity, adopted, in regard to the appointment of ministers, the principle confessedly acted on in the primitive ages of the church, when pastors were elected by the common consent of the clergy and people; and they allowed to the people that potential voice which they considered them to have enjoyed in the earliest times, prior to the introduction of those limitations and restrictions, which they conceived to have been imposed by the clergy at an after period, though still antecedently to the existence of patronage. Accordingly, in the First Book of Discipline, adopted in 1560, treating of "vocation," or calling to the office of the ministry, which, used in a large and general sense, is said to consist of "election, examination, and admission," our reformers declared, that "it appertaineth to the people and to every several congregation to elect their minister." For this purpose the congregation were allowed forty days, and if they failed within that time to present a person for examination, the superintendent, with his council (who exercised the functions now devolved on the presbytery), might present a person to them. It was, however, provided, that if, before the superintendent and his council, or superior church as it is termed, had thus offered them a minister, the inferior church or congregation had agreed upon a person who on examination should be found qualified, the latter was to be preferred to the party nominated by the superintendent and his council; but, on the other hand, if the congregation still failed to offer a person for examination, then they were to be judged unreasonable if they refused the party offered by the superintendent and his council, and might be compelled to receive him, by the censures of the church. In the Second Book of Discipline, agreed to by the church in 1578, it would rather appear, though that has been doubted, that the initiative was intended to be with the presbytery; but at all events the consent of the people was equally required; and it cannot be disputed that, in the intention of the framers of this book, the refusal to consent, though without reasons assigned and judged sufficient by the presbytery, was considered a fatal defect in the vocation to the pastoral office. Such being the system prescribed by the church, it so happened, from the peculiar state of matters in regard to the parochial cures, that for many years after the Reformation it became in practice the general rule for the appointment of ministers. As already noticed, the unannexed parochial benefices, which alone afforded an opportunity for the exercise of patronage, were comparatively few; these were not vacated by the Roman Catholic clergy, but only gradually fell by the death of the subsisting incumbents, when in most cases they were conferred *pleno jure*, by the crown and other patrons, on parties not in the function of the ministry at all. As to the remaining churches, constituting by far the larger proportion of the whole, there was no right of maintenance attached to them; and the ministers of these were appointed, not to a benefice, but simply to a cure of souls, with a chance of procuring a pension out of the general fund of "thirds," by special grant from the Exchequer, or otherwise being left to be supported by the contributions of their flocks. Of these cures, while they remained in this condition, there was of course no patronage, and thus, in by far the greater number of cases, there was no obstacle of the nature of a right of presentation to obstruct the rules prescribed by the church from being freely acted upon. Accordingly there is evidence that in general ministers were appointed during the first period after the Reformation, either by the direct choice of the people, or with their full consent. The manner of appointment was not always uniform, and the voice of the congregation was expressed in diverse ways; but still their voice was required and given; and this is stated by an author intimately acquainted with the records of the times (the late learned Dr M'Crie) to have been the case even where there existed a right of patronage.[1]

When the congregation themselves elected, their wishes appear to have been expressed in the form of a call or invitation, of which the very first election of a pastor amongst the reformers (the choice of Knox as colleague to John Rough by the congregation in the castle of St Andrews) affords an example, or rather the model, agreeably to which the after-practice was fashioned. In accordance with a prior agreement, Rough, after sermon, addressed himself to Knox in these words, as recorded in Knox's own history: "Brother, ye shall not be offended albeit I speak unto you that which I have in charge, even from all those that are here present, which is this: In the name of God and of his Son Jesus Christ, and in the name of those that presently *call* you by my mouth, I charge you that ye refuse not this holy vocation; but as ye tender the glory of God, the increase of Christ's kingdom, the edification of your brethren, and the comfort of me, whom ye understand well enough to be oppressed by the multitude of labours, that ye take upon you the public office and charge of preaching, even as ye wish to avoid God's heavy displeasure, and desire that he shall multiply his graces with you." And in the end, he said to those that were present, "Was not this your charge unto me? And do ye not approve this vocation." They answered, "It was, and we approve it." In general, it would appear that the congregation usually expressed their wishes by commissioners deputed by them to the presbytery, or others having commission to examine and admit, and at times in the form of a letter; but in either way their election assumed substantially the form of a call directed to the party chosen through the presbytery, or others having the power for the time of examination and admission; and, in whatever mode expressed, the consent of the people was in practice a constant requisite to admission. Thus, it was over a church in which, from the absence of patronage in most instances, consequent on the want of benefices, either proper or stipendiary, the practice of admitting the people to an effective voice, in accordance with the polity recognised by the church courts, had already been established, that patronage was gradually extended. By the more effective restriction of presentations in the case of proper benefices to persons who were really to exercise the function of the ministry, and the gradual increase of patronages by the erection of stipendiary benefices by the king, the right of presentation was by degrees again extended over nearly the whole churches of the kingdom. This, however, was not a sudden or violent change, but a progressive superinduction of a right of patronage over churches in which the practice of requiring the consent of the people was already fixed and universally prevalent; and, accordingly, as might have been expected, it continued to co-exist, although there is doubtless a deficiency of evidence in regard to the actual effect on the right of presentation in patronate churches. That the right of presenting on the part of the patron, and the privilege on the part of the people of their consent being required, did, to a certain extent, run counter to each other, and create some obstruction in the settlement of ministers, may fairly be inferred from an act of assembly in 1596, by which it was enacted, that any one seeking a presentation without consent of the presbytery, should be deemed *reus ambitus*, and as such should be rejected; and that effect was in use to be given to this enactment, is clear from a recorded instance in 1602, regarding the parish of Aberlady, in which, while the presentee was found not to have been *reus ambitus*, he having been in ignorance that a presentation was applied for on his behalf, he was obliged to subscribe an obligation, placing his presentation in the hands of the presbytery, and was only sent to the congregation on a leet with others, the privilege of the people in this instance being allowed to supersede in a great measure the right of the patron. By this time, too, the independence of the church had been very nearly extinguished; and, shortly afterwards, episcopacy, with its absolute patronage, was introduced. Even during its subsistence, however, and while the bishops might be compelled by legal diligence to admit a presentee in orders, the people appear to have persisted in claiming a voice, though, as may be supposed, generally without effect; evincing, however, how strongly the previous practice had been rooted in their ronage.

Patronymic.

habits. During all the previous period, and from the restoration of presbytery in 1638, down to the abolition of patronage in 1649, it would rather seem that there was no such form as that of "moderating" in a call. The congregation appear to have met by themselves, without the presbytery or a member of presbytery to moderate in or preside over their proceedings. When, however, the directory of 1649 vested the election in the session, as that body, during a vacancy, was without a moderator, and so incapable of acting as a session unless a moderator were supplied, the directory specially provided that one of the presbytery should be appointed to attend and moderate in the session at their act of election; and this is the origin of the peculiar phrase to "moderate in a call," which is still retained, although the meeting is of the congregation, and the presbytery as a body now usually attend themselves. Under this directory the election of the minister was vested in the elders of the congregation, at that time popularly chosen; and the voice of the people was subjected to this qualification, that the presbytery might disregard the dissent of a majority if they found it to be grounded on causeless prejudices. Under the act 1690, the heritors were joined with the elders, and the qualification enacted as to the voice of the people was more strict, the disapprovers of the person proposed being required to give in their reasons, to be judged of by the presbytery. The right of the heritors and elders under this statute was truly of the nature of a right of presentation, though in the act it was described as the right of "calling" a minister; a phraseology adopted, as is supposed, to render it more palatable to those most hostile to patronage. It was totally different, however, from the proper call by the congregation, although, undoubtedly, for some time after the act 1690 was repealed, a tendency to view the call with reference to that practice is apparent. For several years after the repeal of that act, in 1711, the exercise of the right of patronage was not attempted; and even when presentations began to be issued, they were usually in favour of a party who was likely to be preferred by the people; and the settlements in such cases uniformly proceeded on the call, without the slightest notice of the presentation. In like manner, for many years presentees never ventured to accept unqualifiedly a presentation; and the first instance of unqualified acceptance is said to have occurred in 1731. In the immediately preceding year a presentee had been for the first time since the passing of the 10th of Queen Anne settled in a parish by judgment of the Assembly, in virtue of a presentation, in opposition to the dissent of a majority of the people; and this judgment, which was an adherence to a sentence of the commission, was not rested on the merits of the cause, but was founded on the plea that the sentence of the commission was final and conclusive. After, however, such a settlement had once been accomplished, the Assembly proceeded avowedly on the ground of refusing effect to such dissents; and though several cases subsequently occur in which presentees were refused to be settled in consequence of dissents from the call, or deficiency of signatures to it, the general course of decisions was to sustain the call, without regard to the number of signatures or the extent of opposition (giving occasion to the two great secessions from the Church), till at last, towards the end of the century, the question as to the sufficiency of the call was rarely raised. In all cases, however, down to the present day, the invariable practice has been, that before proceeding to take the presentee on trials, a call is moderated in, and a judgment pronounced by the presbytery sustaining that call. Recently the disputes on this subject have been again revived; and, with a view to establish a definite rule for determining on the validity of the call, the church have passed an enactment, which sets out with a declaration that it is a fundamental law of the church that no pastor be intruded on a congregation contrary to the will of the people, and provides, that if the major part of the male heads of families in communion with the church, and members of the congregation, shall dissent from the call, the presentee shall be rejected. The legal effect of this provision, when acted on by a presbytery, is at present the subject of discussion in the courts of law.

Whatever may ultimately be determined on this point, it is the undisputed privilege of the congregation to give in, at the moderating in the call, specific objections to the presentee, which are not limited to his moral character and doctrine, nor to his talents or learning, but extend to every personal quality, of whatever nature, which may affect his fitness for the charge of the particular parish, viewed with reference to its peculiar characteristics and necessities. At any time, also, during the period allowed for trying the qualifications of the presentee, any of the communicants may proceed against him by libel, on any charge affecting his soundness in doctrine or his moral character; and, finally, when the trials are completed, and the presbytery are assembled for the purpose of ordination, any of them may appear in answer to the edict published to that effect, and demand to be allowed *instanter* to verify sufficient objections to the presentee's life or doctrine. In the mean time, the presbytery have subjected him to trials of a nature similar to those prescribed for licentiates; and if they are satisfied, and no valid objections have been offered, they ordain him to the office of the ministry, and admit him as pastor of the parish.

Besides the right of presentation, the patron was entitled, in the event of a wrongful refusal of his presentee, to retain the stipend in his own hand. By various statutes, however, he was subjected to the obligation of expending it on pious uses within the parish, though such a latitude was given in the interpretation of "pious uses" as to render the disposal of the stipend a matter of some interest to the patron. A recent statute, however, 54 Geo. III. c. 169, has transferred the vacant stipend to the fund for providing annuities to the widows of the clergy. Patrons also, in virtue of the act 1690, c. 23, are, as such, titulars or impropriators of all tithe in their parishes to which no one else can show right; this being a part of the compensation given them for the right of presentation thereby taken from them, and allowed to be retained by them after the right was restored; and, finally, if also heritors in the parish, they have right to the first choice of a family seat in the division and allotment of the area of the church. (R. R. R. R.)

PATRONYMIC, amongst grammarians, is applied to such names of men or women as are derived from those of parents or ancestors. Patronymics are derived from the father, as Pelides, that is, Achilles the son of Peleus; or from the mother, as Philyrides, that is, Chiron the son of Philyra; or from the grandfather on the father's side, as Æacides, or Achilles the grandson of Æacus; or from the grandfather by the mother's side, as Atlantiades, Mercury the grandson of Atlas; or, lastly, from the kings and founders of nations, as Romulidæ, the Romans, so called from their founder King Romulus. The terminations of Greek and Latin patronymics are chiefly four, viz. *des*, of which we have already given examples; *as*, as Thaumantias, that is, Iris the daughter of Thaumas; *is*, as Atlantis, that is, Electra, the daughter of Atlas; and *ne*, as Nerine the daughter of Nereus. Of these terminations, *des* is masculine; and *as*, *is*, and *ne* are feminine; *des* and *ne* are of the first declension, *as* and *is* of the third. The Russians, in their usual mode of address, never prefix any title or appellation of respect to their names; but persons of all ranks, even those of the first distinction, call each other by their Christian names, to which they add a patronymic. These patronymics are formed in some cases by adding Vitch, the same as our Fitz, to the Christian name of the father; and in others by

Of or Ef. The former is applied only to persons of condition, the latter to those of inferior rank.

PATROS, mentioned by Jeremiah and Ezekiel, appears from the context to mean a part of Egypt. Bochart thinks it denotes Upper Egypt; the Septuagint translate it the country of *Pathure;* Pliny speaks of the *Nomos Pathurites* in the Thebais; and Ptolemy mentions *Pathyris,* which was probably the metropolis. From the Hebrew appellation *Patros* comes the gentilitious name *Pathrusim.*

PATTAN, a town of Northern Hindustan, in the valley of Nepaul, situated at the distance of a mile and a half from the present capital of Catmandoo, from which it is separated by the Bhagmutty river. It stands on a small but elevated plain, and is said, whilst Patu existed as an independent state, to have comprehended 24,000 houses. It is a neater town than Catmandoo, and contains some handsome houses. Long. 85. 40. E. Lat. 27. 31. N.

Pattan, a town of Hindustan, in the province of Aurungabad, belonging to the nizam, thirty-eight miles south-west of Aurungabad. Long. 75. 33. E. Lat. 19. 29. N. It is the chief town of a district of the same name, in the province of Gujerat, situated about the 24th degree of north latitude. The country is but thinly inhabited, and is much exposed to the ravages of the numerous predatory tribes in this quarter of Gujerat. It contains the ancient capital of Gujerat, and is bounded on the west by the great salt lake called the Runn.

PATTEALAH, a town of Hindustan, in the province of Delhi, and district of Sirhind, and the residence of one of the Sikh chiefs. It is a place of considerable extent, and is now the most flourishing town in the district. It is surrounded with a strong mud wall, and has in the centre a square citadel, which contains the palace of the rajah or chief. It is said to have been founded about the year 1465, by Rai Ram Deo. It contains numerous tombs of devout Mahommedans. Long. 75. 38. E. Lat. 30. 18. N.

PATTI, a town on the northern coast of the island of Java, about 380 miles east of Batavia.

PATTIARY, a town of Hindustan, in the province of Agra, and district of Ferrukabad. Long. 79. 25. E. Lat. 27. 37. N.

PATTUR, or Puttugotta, a town of Bengal, in the district of Boglipore, pleasantly situated at the foot of a range of hills on the eastern bank of the Ganges, which is here very steep. Near this place is a rock covered with rude representations of the Hindu deities.

PAU, an arrondissement of the department of the Lower Pyrenees, in France, 641 square miles in extent. It comprehends eleven cantons, divided into 221 communes, and contains 110,100 inhabitants. The capital is a city of the same name, the seat of the departmental government and of the courts of law. It stands on the river Gave de Pau, in a fine valley, with romantic views of the neighbouring mountains. It is a well-built city, with a fine place or square, 1600 houses, and 11,600 inhabitants. Amongst the curiosities are the palace or castle in which Henry IV. of France was born. It has some manufactures of table and other linen, and others of cottons and hats, and considerable trade in wine, and especially in a celebrated kind of hams. Long. 0. 14. W. Lat. 43. 15. N.

Pau, one of the Tefee Islands, in the South Pacific Ocean, celebrated for sandal-wood. The inhabitants are said to be cannibals, although some Englishmen have of late resided on the island.

PAUCARTAMBO, a province of Peru, in the department of Cuzco, and situated to the east of the province and city of that name. It is traversed by a considerable stream of the same name, which flows into the Urubamba, one of the southern affluents of the Amazons. Considerable quantities of cocoa-leaf are annually exported from this province, and the land also produces rice, cacao, yucas, camotes, Indian corn, pine-apples, plantains, and other fruits, all in great abundance, and of most excellent quality. A large return, however, is only to be expected when the ground has been carefully cultivated; and this is seldom the case, owing to the indolent habits of the Indians, who are content to live for the most part on chuno or blanched potato, sesina or sun-dried meat, and aji or capsicum. Vegetables are scarcely ever seen, although the soil and climate admit of the production of most sorts for the table. Orange trees flourish remarkably well, and yield delicious fruit; but only a very few have been planted, so lazy and indifferent to the natural fertility of their country are the Indians. The Chunchos, as they are called, are, besides, a filthy, immoral people, and live so wretchedly that they suffer dreadfully from ague and fever, which carries them off in great numbers, there being no one exercising medical skill amongst them. Their favourite occupation is travelling with bow and arrow in hand through the forests in pursuit of game, monkeys, wild boars, and other animals. Paucartambo, the capital of the province, and situated fifteen leagues east-north-east from Cuzco, is thus described by General Miller, who traversed this hitherto unknown region in the year 1835. "This town, situated in a deep ravine, and on the banks of a mountain stream, was once of considerable importance, owing to its connection with the valleys twenty leagues distant, at the easternmost foot of the Andes, which formerly contained three curatos, and upwards of one hundred estates, principally cocoa-leaf plantations. Of the latter, owing to sickness, hostile inroads of the Indians, &c. only six now remain. Besides other causes of decay, one third of the houses of the town of Paucartambo have been carried away by its river within these few years, and it now contains only about some hundred inhabitants, mostly of Spanish blood, and distinguished for their superior intellect, good countenances, and urbane bearing, as compared with the rest of the population in the department of Cuzco."

PAUKPUTTAN, a town of Hindustan, possessed by native chiefs, in the province of Mooltan, 130 miles east by south from the city of Mooltan. Long. 73. 30. E. Lat. 30. 20. N.

PAUL, originally Saul, an apostle of Jesus Christ, and author of several portions of the New Testament canon. Though a native of Tarsus, a city of Cilicia,[1] he was the son of Jewish parents, belonging to the tribe of Benjamin.[2] From his father he inherited the rights of Roman citizenship,[3] which had probably been conferred upon some of his ancestors for some important services rendered to the commonwealth;[4] and it is with great probability supposed, that the cloak and parchments which he so earnestly charged Timothy to bring with him to Rome, were the Roman toga and the certificates of his citizenship, which he expected might be of use to him in his anticipated trial before the emperor. The name *Saul* (שאול), which he received at his birth, and which signifies "the longed-for, the desired," would seem to indicate that he was the first-born son of his parents, and that his birth was viewed by them as an answer to many prayers; that he was not, however, their only child, is apparent from Acts, xxiii. 16, where mention is made of his "sister's son." His father being of the sect of the Pharisees, probably devoted him from his infancy to the service of religion; and with this view he seems to have received such education as appeared most calculated to fit him for the duties to which he was destined. At that time Tarsus was eminently distinguished for its cultivators of philosophy, and every other department in the circle of instruction (σπουδὴ πρὸς τε φιλοσοφίαν καὶ τὴν ἄλλην ἐγκύκλιον ἅπασαν παιδειάν);[1] but to what extent the future apostle of Christianity was indebted to the labours of such teachers for his early education, no means are left us of judging. It is probable that his obligations were not very great; for as his ultimate destination was to the office of an expounder of the Jewish law and traditions, it does not appear likely that he would be sent by his parents to occupy himself with the literature and philosophy of those whom the Jews despised as outcasts, as well from the light as from the favour of heaven. At the same time, it cannot be denied that his residence in a city where the study of the liberal sciences was so assiduously and successfully prosecuted as to place it upon a par with "Athens, Alexandria, or any other place that could be named in which schools and studies are to be found,"[2] must have had a powerful influence in refining his taste, and liberalising and expanding his views. It was at Jerusalem, however, the centre of the Jewish world, that the most important part of his education was received. At an early age, in his twelfth or fourteenth year, as is supposed,[3] he was brought to this city, and placed under the instruction of Gamaliel, one of the most famous teachers of Jewish learning at that time.[4] Here he finished his education as a Pharisee, and at the same time, according to the custom of the Jews, acquired a mechanical art, that of a σκηνοποιός, which some render "a mechanist,"[5] others "a hair-cloth-maker,"[6] others "a maker of tapestry or carpeting," and others, with most apparent propriety, as in our version, "a tent-maker."[7] By this he probably supported himself during the time he was engaged in the prosecution of his studies, as we know he was in the habit of doing at an after-period whilst engaged as an apostle. How long he abode in Jerusalem at this time, or whether he returned to Tarsus at all before his conversion, are points on which no certain information can now be obtained. In the history of the early church, he is introduced to us, for the first time,[8] as "a young man,"[9] whose zeal for the religion of his fathers had prompted him to assume the character of an active persecutor of those who had forsaken that religion for the faith of Christ. On the occasion of the martyrdom of Stephen, he appears in the capacity of an abettor, and in some respects a sort of superintendent, of the act; and immediately after this, he, as if rendered more ferocious by the blood he had assisted in shedding, kindled the flames of a relentless and unsparing persecution, in which all, without respect of age or of sex, who had professed the hated religion, were compelled to blaspheme the name of Jesus, or obliged to endure the utmost indignities and the most condign punishments.[11] It was whilst engaged in these cruel efforts of a dark and bigoted zeal that he was made to experience that extraordinary change of opinion and feeling which gave a new direction to all his energies, and led him to devote his life to the advancement of that cause which he at first deemed it serviceable to God to oppose and destroy. Having obtained from the rulers of his nation a commission to go to Damascus, in which city the Jews were very numerous, and where also the new religion had obtained a footing, for the purpose apparently of arresting such of the Christians as had fled to that city, and bringing them back bound to Jerusalem, he was himself arrested by a higher power, and made to feel his utter impotency when attempting to oppose the cause of Christ. Whilst crossing the plain to the south of Damascus, about noon-day, and at a short distance from that city, he was suddenly surrounded by a miraculous light from heaven, which had the effect of so paralyzing him, that he fell to the ground, whilst a voice addressed to him the thrilling question, "Saul, Saul, why persecutest thou *me?*" In answer to the inquiry which he made in return, the voice said, "I am Jesus of Nazareth, whom thou persecutest; but arise and go into the city, and it shall be told thee what to do." Confounded, humbled, and agitated, he obeyed the heavenly vision; and as the brilliancy of the light had obscured his vision, he was led by his astonished attendants into the city, where he remained in a state of deep dejection for three days and nights, during which he tasted neither meat nor drink. From this painful condition he was relieved by the visit of a man named Ananias, who, at the command of Christ, sought him out, welcomed him as a brother, and baptized him into the profession of Christianity.[12]

---

[1] Acts, xxii. 3, &c.

[2] Philip. iii. 5.

[3] Acts, xxii. 25-28.

[4] The opinion that the natives of Tarsus enjoyed the *jus civitatis* as a birthright, is not supported by evidence. The fact of that city's having been created by Augustus an *urbs libera* (Plin. v. 27) does not lead to any conclusion as to the possession by its natives of the right of Roman citizenship; and, from Acts, xxi. 39, compared with xxii. 24, 27, it may be inferred, that as the chief captain knew Paul to be a native of Tarsus, and yet was ignorant of his Roman citizenship, these two were not necessarily conjoined.

The first three years after his conversion were spent by

[9] Nothing satisfactory, however, can be drawn from this as to Paul's age at this period, for the word νεανιας is applied with much indefiniteness to persons of from twenty-four to forty years of age. Perhaps his age was about thirty.

[11] Acts, viii. 1–3; xxvi. 10, 11.

[12] Acts, ix. 1–18. The conversion of such a man, at such a time, and by such means, furnishes one of the most complete proofs that have ever been given of the divine origin of our holy religion. That Saul, from being a zealous persecutor of the disciples of Christ, became all at once a disciple himself, is a fact which cannot be controverted, without overturning the credit of all history. He must therefore have been converted in the miraculous manner in which he himself said he was, and of course the Christian religion be a divine revelation; or he must have been either an impostor, an enthusiast, or a dupe to the fraud of others. There is not another alternative possible.

If he was an impostor, who declared what he knew to be false, he must have been induced to act that part by some motive. (See MIRACLE.) But the only conceivable motives for religious imposture are, the hopes of advancing one's temporal interest, credit, or power; or the prospect of gratifying some passion or appetite under the authority of the new religion. That none of these could be St Paul's motive for professing the faith of Christ crucified, is plain from the state of Judaism and Christianity at the period of his forsaking the former and embracing the latter faith. Those whom he left were the disposers of wealth, of dignity, of power, in Judea; those to whom he went were indigent men, oppressed, destitute of all means of improving their fortunes. The certain consequence, therefore, of his taking the part of Christianity, was the loss not only of all that he possessed, but of all hopes of acquiring more; whereas, by continuing to persecute the Christians, he had hopes rising almost to a certainty of making his fortune by the favour of those who were at the head of the Jewish state, to whom nothing could so much recommend him as the zeal which he had shown in that persecution. As to credit or reputation, could the scholar of Gamaliel hope to gain either by becoming a teacher in a college of fishermen? Could he flatter himself, that the doctrines which he taught would, either in or out of Judea, do him honour, when he knew that "they were to the Jews a stumbling block, and to the Greeks foolishness?" Was it, then, the love of power that induced him to make this great change? Power! over whom? over a flock of sheep whom he himself had assisted to destroy, and whose very Shepherd had lately been murdered? Perhaps it was with the view of gratifying some licentious passion, under the authority of the new religion, that he commenced a teacher of that religion. This cannot be alleged; for his writings breathe nothing but the strictest morality, obedience to magistrates, order, and government, with the utmost abhorrence of all licentiousness, idleness, or loose behaviour, under the cloak of

Paul in Arabia,[1] where he received the Gospel he preached "by revelation from Christ," and where in solitude and quiet he was doubtless engaged in training himself for the work in which he was about to engage. On his return to Damascus, he openly appeared as a preacher of Christianity, a circumstance which the Jews felt to be so injurious to their cause, that they sought, by the aid of the governor, who was in all probability himself a Jew, to put him to death. Having by the aid of his Christian brethren escaped their malice, he betook himself to Jerusalem, where, after the fears of the brethren, who remembered his former enmity, but had not heard of his subsequent conversion to Christianity, had been removed by the testimony of his friend and companion Barnabas, he was gladly welcomed amongst them, and permitted to occupy that rank to which Christ had called him.[2] The enmity of the Jews again compelled him to change his residence. After being fifteen days in Jerusalem, he went to Cæsarea, and thence to his native city Tarsus, where he abode for several years.[3] In the mean time, Christianity, which had hitherto been preached only to the Jews, had received some adherents from amongst the Gentiles at Antioch; and this led to the mission of Barnabas from Jerusalem, for the purpose of instructing and regulating the church that had been formed there. Barnabas, after some time, finding the need of assistance and counsel, went to Tarsus, and returned with Paul to Antioch, where they abode for a year, occupied in united efforts for the promulgation of Christianity. At the close of that period, they were sent to Jerusalem by the Christians at Antioch, with the contributions which had been made by them on behalf of their brethren in Judea, who were suffering from the effects of a dearth.[4] This was Paul's *second* visit to Jerusalem since his conversion. After some months, they again returned to Antioch, accompanied by John Mark, the nephew of Barnabas. The cause of Christianity by this time had begun to flourish in that city, and several persons had been received into the church who were qualified to act as teachers to the rest. This rendered it the less necessary that Paul and Barnabas should remain any longer with them; and accordingly, shortly after their return, the church received a special command from heaven to set them apart to general missionary work. In obedience to this command, they were sent forth; and, accompanied by John Mark, who, however, soon deserted them and returned to Jerusalem, they visited Seleucia, Cyprus, Perga in Pamphylia, Antioch in Pisidia, Iconium, Lystra and Derbe, cities of Lycaonia (at the former of which, in consequence of Paul's curing a cripple, the people were on the point of offering him and his companion divine honours, under the impression that the gods had come down in the likeness of men, but were restrained by the vehement expostulations of those for whom these impious honours were designed; and in a few days after, they had so completely changed their minds, that, at the instigation of the Jews, they stoned Paul, and left him for dead); and then retracing their steps, they returned by way of Attalia, a city of Pamphylia, by sea to Antioch, where they rehearsed to the church all that God had

---

religion. We nowhere read in his works, that saints are above moral ordinances; that dominion is founded in grace; that monarchy is despotism which ought to be abolished; that the fortunes of the rich ought to be divided amongst the poor; that there is no difference in moral actions; that any impulses of the mind are to direct us against the light of our reason and the laws of nature; or any of those wicked tenets by which the peace of society has been often disturbed, and the rules of morality often broken, by men pretending to act under the sanction of divine revelation. He makes no distinctions, like the impostor of Arabia, in favour of himself; nor does any part of his life, either before or after his conversion to Christianity, bear any mark of a libertine disposition. As amongst the Jews, so amongst the Christians, his conversation and manners were blameless. It has been sometimes objected to the other apostles, by those who were resolved not to credit their testimony, that having been deeply engaged with Jesus during his life, they were obliged, for the support of their own credit, and from having gone too far to return, to continue the same professions after his death; but this can by no means be said of St Paul. On the contrary, whatever force there may be in that way of reasoning, it all tends to convince us that St Paul must *naturally* have continued a Jew, and an enemy to Christ Jesus. If *they* were engaged on one side, *he* was as strongly engaged on the other. If shame withheld them from changing sides, much more ought it to have stopped him, who, from his superior education, must have been vastly more sensible to that kind of shame than the mean and illiterate fishermen of Galilee. The only other difference was, that *they*, by quitting their Master after his death, might have preserved themselves; whereas *he*, by quitting the Jews, and taking up the cross of Christ, certainly brought on his own destruction.

As St Paul was not an impostor, so it is plain he was not an enthusiast. Heat of temper, melancholy, ignorance, and vanity, are the ingredients of which enthusiasm is composed; but from all these, except the first, the apostle appears to have been wholly free. That he had great fervour of zeal, both when a Jew and when a Christian, in maintaining what he thought to be right, cannot be denied; but he was at all times so much master of his temper, as, in matters of indifference, to "become all things to all men;" with the most pliant condescension bending his notions and manners to theirs, as far as his duty to God would permit; a conduct compatible neither with the stiffness of a bigot nor with the violent impulses of fanatical delusion. That he was not melancholy, is plain from his conduct in embracing every method which prudence could suggest to escape danger and shun persecution, when he could do it without betraying the duty of his office or the honour of his God. A melancholy enthusiast courts persecution, and when he cannot obtain it, afflicts himself with absurd penances; but the holiness of St Paul consisted only in the simplicity of a godly life, and in the unwearied performance of his apostolical duties. That he was ignorant, no man will allege who is not grossly ignorant himself; for he appears to have been master not only of the Jewish learning, but also of the Greek philosophy, and to have been very conversant even with the Greek poets. That he was not credulous, is plain from his having resisted the evidence of all the miracles performed on earth by Christ, as well as those that were afterwards worked by the apostles; to the fame of which, as he lived in Jerusalem, he could not possibly have been a stranger. And that he was as free from vanity as any man that ever lived, may be gathered from all that we see in his writings, or know of his life. He represents himself as the least of the apostles, and not meet to be called an apostle. He says that he is the chief of sinners; and he prefers, in the strongest terms, universal benevolence to faith, and prophecy, and miracles, and all the gifts and graces with which he could be endowed. Is this the language of vanity or enthusiasm? Did ever fanatic prefer virtue to his own religious opinions, to illuminations of the Spirit, and even to the merit of martyrdom?

Having thus shown that St Paul was neither an impostor nor an enthusiast, it remains only to be inquired, whether he was deceived by the fraud of others; but this inquiry needs not be long, for who was to deceive him? A few illiterate fishermen of Galilee? It was *morally* impossible for such men to conceive the thought of turning the most enlightened of their opponents and the most cruel of their persecutors into an apostle, and to do this by a fraud in the very instant of his greatest fury against them and their Lord. But could they have been so extravagant as to conceive such a thought, it was *physically* impossible for them to execute it in the manner in which we find his conversion to have been effected. Could they produce a light in the air which at mid-day was brighter than the sun? Could they make Saul hear words from out of that light which were not heard by the rest of the company? Could they make him blind for three days after that vision, and then make scales fall off from his eyes, and restore him to sight by a word? Or, could they make him and those who travelled with him believe that all these things had happened, if they had not happened? Most unquestionably no fraud was equal to all this.

Since, then, St Paul was neither an impostor, an enthusiast, nor deceived by the fraud of others, it follows that his conversion was miraculous, and that the Christian religion is a divine revelation. See Lyttleton's "Observations on the Conversion of St Paul;" a treatise to which it has been truly said, that infidelity has never been able to fabricate a specious answer, and of which this note is a very short and imperfect abridgement.

done by them. This formed the apostle Paul's *first* great missionary tour.[1]

After some time spent at Antioch, he and Barnabas again went up to Jerusalem, for the purpose of consulting the apostles and elders in regard to some dissensions which had occurred in the church at Antioch, as to the obligation on Gentile converts of the Mosaic ceremonial. This gave occasion to the holding of a council at Jerusalem, at which, after much disputing, it was at length agreed unanimously, at the suggestion of the apostle James, that they should lay no stumbling-block in the way of their Gentile brethren, by requiring of them more than simply that they should abstain from meats offered to idols, from uncleanness, from things strangled, and from blood, whether pure or mixed with anything else. A letter to this effect was written to the church at Antioch in the name of the church at Jerusalem; and with this, two of the members of this church, Judas and Silas or Silvanus, were appointed to accompany Paul and Barnabas to Antioch.[2] By these means the difference of opinion amongst the brethren was removed, and the church restored to peace. This led Paul to propose to Barnabas another missionary tour, to which that faithful fellow-labourer having consented, they were on the verge of departure, when an unhappy contention, arising out of a determination on the part of Barnabas to take with them his nephew John Mark, a step which Paul firmly resisted, on the ground of Mark's former conduct in deserting them, produced a rupture between these two eminent individuals, and led to their prosecuting a separate course.[3] Whilst Barnabas, in company with his nephew, went to Cyprus, Paul, attended by Silas, went towards the east, and, passing through Syria and Cilicia, revisited the scenes of his former labours and sufferings in Lycaonia. At Lystra he found Timothy, a young man who had been probably converted to Christianity on the occasion of the apostle's former visit, and who was so highly commended by the church in that place that Paul selected him as the companion of his travels, having previously ordained him by the imposition of the hands of the presbytery.[4] Accompanied by him and Silas, the apostle next passed through the regions of Phrygia and Galatia, and avoiding Asia strictly so called, which he was forbidden by the Holy Spirit to enter, as well as Bithynia, they came by way of Mysia to Troas, a city and port on the borders of the Hellespont. Here he was directed by an apparition in a vision to go into Macedonia; and accordingly, with his companions, having crossed to Samothracia, and thence to Neapolis, a seaport of Thrace, he arrived in due course at Philippi. Here they remained for some time, and made many converts, amongst others the jailor of the prison, into which Paul and Silas had been thrust after having been scourged, in consequence of a charge which had been brought against them as disturbers of the peace of the city, by a set of impostors whose trade they had destroyed by expelling an evil spirit from a female slave who brought them much gain by her skill in soothsaying. From Philippi they passed through Amphipolis and Apollonia, cities of Macedonia, to Thessalonica, where, though they abode only a short time, they preached the gospel with great success. A tumult having arisen at the instigation of the Jews, the Christian converts, fearing for their safety, sent them by night to Berea, another city of Macedonia, about forty miles west of Thessalonica, where they were favourably received by their Jewish brethren, until a party which had followed them from Thessalonica stirred up a persecution against them. This determined Paul to go to Athens, whilst Timothy and Silas, as less obnoxious to the Jews, remained at Berea. It does not appear to have been the apostle's intention in the first instance in visiting Athens to preach the gospel there, at least until Timothy and Silas, to whom he had sent a message on his arrival, requiring them to join him, should have arrived; but as he waited for them, the sight of a city like that of Athens, entirely given to idolatry, so stirred and excited his spirit that he could no longer refrain; and accordingly, in the synagogues he disputed with the Jews, and in the market-place with such as he met. This led to his coming into contact with certain Stoic and Epicurean philosophers, by whom he was contemptuously invited to unfold his new doctrines, and describe the strange deities of which they supposed him to be the votary; and for this purpose he was taken to the Areopagus, where, with admirable tact, he exposed the follies of their idolatry, and commended to them the worship of the one living and true God, in the midst of a vast assemblage of people, on many of whom a favourable impression was produced by his address.[5] Having been joined by Timothy,[6] and in all probability by Silas also,[7] he sent the former again to Macedonia, and either retaining the latter in his company, or despatching him to some other quarter, he himself passed over to Corinth.[8] On the occasion of this his first visit to that city, he supported himself by his labours as a tent-maker, in company with a pious couple named Aquila and Priscilla, who had taken refuge in Corinth after having been expelled from Rome by an edict of Claudius Cæsar against the Jews; and at the same time he availed himself of every opportunity of urging the gospel of Christ upon the acceptance both of Jews and Greeks. Here he was rejoined by Silas and Timothy, with whom he continued a year and a half in active exertion for the advancement of Christianity. By the persevering enmity of his former opponents the Jews, he was again compelled to leave Corinth, and betake himself, along with Aquila and Priscilla, to Ephesus. Here he abode at this time only a few days, having been commissioned by a divine revelation to go up to Jerusalem in time for the approaching feast of the passover. On this journey, which ended in his paying his *fourth* visit to Jerusalem since his conversion, he was accompanied by Barnabas, with whom his former friendship had been re-established, and Titus, a Greek, who seems to have been a convert of Barnabas. After a brief residence there, he returned to Antioch, and so finished his second great apostolic tour.[9]

At Antioch he abode for some time, and then commenced another extensive tour, accompanied, as is supposed, by Titus. Passing through Phrygia and Galatia, where he revisited the churches he had formerly planted, he arrived at Ephesus. This city stood in the same relation to the region of Hither Asia in which Jerusalem stood to Palestine, Antioch to Syria, Corinth to Achaia, and Rome to the west; and accordingly the apostle made it his head-quarters for three years, during which time he was occupied in making converts in the city, and in paying short visits to the surrounding places, and to Crete and other islands of the adjoining archipelago. With so much success were his labours attended in Ephesus, that the revenues of those who were interested in the support of the idolatrous worship of the tutelar goddess of the city, Diana, began to be affected; and at the instigation of one of these, by name Demetrius, a silversmith, who carried on an extensive manufacture of miniature representations of the famous temple of Diana at Ephesus, a popular tumult was excited against the apostle, which was with difficulty appeased by the calm and sagacious conduct of the γραμματεύς, or town-clerk, who, along with others of the chief men in the place, seems to have been friendly towards Paul. Whether this tumult had any effect in quickening the apostle's determination to leave Ephesus, is uncertain; it is clear, however, that he had come to that determination before it happened.[1] By divine direction, he had resolved to go to Macedonia; and accordingly, shortly after the tumult, he departed from Ephesus, and went by way of Troas to Philippi. There he seems to have remained a considerable while, for, during his residence at Philippi as his head-quarters, he preached the gospel in all the surrounding districts, even as far as to Illyricum, on the eastern shore of the Adriatic.[2] Leaving Philippi, he paid a second visit to Corinth, where he abode three months, and then returned to Philippi, having been frustrated in his intention of proceeding through Syria to Jerusalem by the malice of the Jews. From Philippi he sailed for Troas, where he abode seven days; thence he journeyed on foot to Assos; and thence he proceeded by sea to Miletus, having visited several of the intermediate places. At Miletus he had an affecting interview with the elders of the church at Ephesus, to whom, in the prospect of seeing them no more, he gave a solemn and impressive charge, and bade them farewell. From Miletus he sailed for Syria, and, after visiting several intermediate ports, landed at Tyre, where he remained seven days. Thence he journeyed by way of Ptolemais and Cæsarea to Jerusalem, which he visited on this occasion for the *fifth* time since his conversion.[3]

[8] 1 Thess. iii. 1, 2, 6, compared with Acts, xviii. 5.

[9] Acts, xviii. 1–22.

At Jerusalem he recounted to the whole church the events connected with the progress of Christianity of which he had been witness, and, apparently to quiet the scruples of some Jewish converts, who thought he had too lax and incorrect a view of the obligation of the Mosaic ritual, he united himself, at the suggestion of the apostle James, to four persons who had taken upon them the vows of Nazarites, and, entering with them into the temple, signified to the priest that he would pay the cost of the sacrifices which were necessary to absolve them and him from the vow. Whatever effect this compliance had on the minds of his scrupulous brethren, it procured for him no mitigation of the hatred with which he was regarded by the unconverted Jews. On the contrary, so eager was their zeal against him, that, before his vow was accomplished, they seized him in the temple, and would have put him to death, had not Lysias, commander of the Roman cohort in the citadel adjoining the temple, brought soldiers to his rescue. By his permission, and under his protection, Paul addressed to the infuriated mob an apology for himself, in which he set forth the main circumstances of his life from the beginning up to the period when he opened his commission to the Gentiles. At first he was listened to with attention, but as soon as he spoke of placing the Gentiles on a par with the Jews, they interrupted him with execrations, and shouted, "away with such a fellow from the earth, for it is not fit that he should live."[4] The Roman commander seeing these demonstrations of popular resentment, and being ignorant of what Paul had been saying, from the address having been uttered in the Hebrew tongue, imagined that he must be some execrable criminal, and gave orders that he should be brought into the fort, in order that he might by scourging compel him to confess his crime. From this indignity Paul saved himself by asserting his privileges as a Roman citizen, to bind or scourge whom was strictly forbidden by law. Next day the chief captain brought him before the Sanhedrim, for the purpose of hearing what it was that was urged against him; and here Paul again entered into a defence of his conduct, in the course of which he professed his attachment to the doctrine of a corporeal resurrection, and thereby stirred up a fierce controversy between the two parties composing the Sanhedrim, the Pharisees and the Sadducees, the former of whom maintained, whilst the latter denied, this doctrine. So angry and vehement did this discussion become, that the chief captain, fearing for the safety of his prisoner, whom, as a Roman citizen, he was bound to protect, commanded his soldiers to go down and remove him from amongst the combatants, into the fort. Upon the day following, above forty of the Jews entered into a solemn engagement neither to eat nor drink until they had killed Paul, and for this purpose proposed to the chief priests to invite him to a conference, in the hope that they might have an opportunity of assaulting him on his way from the fort. This scheme was rendered abortive by intelligence of it having been conveyed to Lysias by Paul's sister's son, who, alongst with his mother, seems to have been an early convert to Christianity.[5] Matters assuming this desperate aspect, Lysias determined to bring the whole under the consideration of the procurator; and, accordingly, placing Paul under the protection of a sufficient escort, he sent him to Cæsarea, with a letter to Felix, explaining the reasons of this step. After five days, Felix held a court, at which Paul and his accusers were brought together, and both parties heard at full length. The defence of the apostle was triumphant; but Felix, unwilling to offend the Jews, remanded him, under the pretence of obtaining farther information from Lysias. Some days afterwards, he summoned him again to his tribunal, in order that he and his wife Drusilla, who was a daughter of Herod Agrippa, might hear him "concerning the faith in Christ;" on which occasion, the apostle, with all that fearless zeal and faithfulness for which he was distinguished, expostulated so forcibly with the procurator in regard to those vices for which he was notorious, that Felix trembled, and hastily dismissed him from his presence. Shortly after this, Felix was removed from his office, and was succeeded by Porcius Festus, before whom the Jews again brought their charges against Paul. When both parties came to be heard, Paul perceived so evident a disposition in the new governor to favour the Jews, that he felt constrained to avail himself of the privilege which, as a Roman citizen, he possessed, of removing his cause from the province to the metropolis, by appealing to the emperor. This led to his being sent to Rome, but not before he had been again heard by Festus, attended by King Agrippa and his wife Bernice, by whom he was adjudged to have done nothing worthy of death or of bonds, so that he might have been set at liberty had he not appealed unto Cæsar. His voyage to Rome was long and disastrous. After coasting along Syria as far as Sidon, they struck across to Myra, a port of Lysia, having passed under Cyprus; thence they sailed slowly towards Cnidus, and thence, in consequence of the wind being contrary, to Crete, where they with difficulty put into a port on the southern side of that island, called the "The Fair Haven," near the city of Lasea. The season being now far advanced, Paul advised the centurion to proceed no farther; but the place not being suitable for wintering in, and the weather promising favourably, his advice was disregarded, and they again set sail, intending to reach Phœnice, a port in the same island, and there to winter. Scarcely, however, had they ventured to sea when the apostle's prediction was verified; for a boisterous wind arose and drove them at its mercy across the Mediterranean. In this state they continued for fourteen days, at the close of which they were shipwrecked on the coast of Malta, but without any loss of life. Here the apostle and his company remained for three months, during which time he was actively employed in

instructing the inhabitants, and performed many miracles for their benefit. On the approach of spring, they availed themselves of a ship of Alexandria that had wintered in the island, and set sail for Syracuse, where they remained three days; thence they crossed to Rhegium, and thence along the coast to Putcoli, from which place he journeyed by land to the imperial city. Here he was delivered by the centurion in whose charge he had come from Cæsarea, to the captain of the guard, who, with great lenity, permitted him to dwell in his own hired house, under the charge of a soldier.[1]

The sacred historian closes his narrative by informing us that Paul continued in this state of easy imprisonment for "two years, receiving all that came to him, preaching the kingdom of God, and teaching those things which concern the Lord Jesus Christ, with all confidence, no man forbidding him." Of the subsequent events of the apostle's life, consequently, we have much less direct and certain information; and from this has arisen much diversity of opinion on the subject. By many it is supposed that this his first imprisonment at Rome was his last, and that he perished in the persecution which Nero excited against the Christians, by representing them as the agents in the burning of the city; whilst others contend that he was set at liberty before that event, and that he set out on another great missionary tour to the west, in the course of which he preached the gospel throughout Spain, and, according to some, in Britain also;[2] revisited Ephesus and other places in Lesser Asia, passed over to Crete, returned to Ephesus, passed through Troas into Macedonia, thence to Nicopolis in Epirus, Dalmatia in Illyricum, and back again to Asia, when he was apprehended and conveyed to Rome the second time, where he suffered martyrdom. By some who hold this latter opinion the order of places visited is completely reversed, and Paul is supposed to have commenced his tour in Asia, and ended it in Spain. It would require a much larger space than this article can be permitted to occupy, to enter into any examination of the arguments and evidence on both sides of this question. Suffice it to remark, that whilst the whole subject is involved in much uncertainty, and whilst little more than probable conjecture can be furnished for the details of either hypothesis, the preponderance seems to be in favour of the latter. Our readers will probably be satisfied of this by a reference to what has been written on it by Mr Greswell and Professor Neander; the former of whom contends for it with all the zeal of an advocate, whilst the latter admits it with all the deliberation of a cautious and impartial judge.[3]

In the above sketch of the principal events of the apostle's life no attempt has been made to assign to each its proper date. This has resulted from the great perplexity in which this part of the subject is involved, and the consequent inexpediency of adopting any particular chronology without assigning the reasons on which it is founded; a course which would have extended this article greatly beyond its proper bounds. We have deemed it preferable, therefore, to present, in the first instance, the leading facts in the history of Paul in the order of their occurrence, and shall now furnish a table of the dates assigned to the more important of these in those systems of chronology which are most deserving of notice, leaving it with our readers to consult the works in which they are unfolded, for the arguments by which they are respectively supported.

During the brief intervals of comparative ease which the apostle enjoyed amid his arduous and almost incessant exertions as a preacher of Christianity, he wrote several treatises, more or less elaborate, both of a doctrinal and a practical nature, in the shape of epistles to different churches. Of these, thirteen, avowedly of his composition, and one that is with great probability ascribed to him (the Epistle to the Hebrews)[8] have come down to us; and there is good reason to believe that in these we have the whole of those compositions which, as an apostle of Jesus Christ, he gave to the church. It is supposed, indeed, by many distinguished biblical critics, that there is evidence in the first of his extant epistles to the Corinthians, of his having written one to that church antecedently to either of these; but the basis of evidence on which this rests is at best very slender, and the support which it lends to what is raised on it very doubtful.[9] In what order these epistles were written, and what date is to be assigned to each, are points on which much discussion has been expended. The following lists present the results of the investigations of Greswell and Neander; and the agreement of these two very able and independent inquirers in so many particulars may be safely regarded as an argument in favour of the general correctness of that scheme which, with trifling variations, both adopt.

Neander regards the Epistle to the Hebrews as of uncertain authorship, but deems it probable that it was written about the period of the apostle's martyrdom, by "some apostolic man of the Pauline school."[10]

In perusing the history and the writings of St Paul, it is impossible not to be struck with the amazing energy of thought and action by which he was characterized. The conception of *power* is impressed upon the mind by every view of his history, and the study of every page of his writings. The ease with which he threw off the prejudices of

Judaism, notwithstanding the deep hold which these had taken of his mind; the rapidity with which he expanded his thoughts to embrace the vast conceptions unfolded by the free offers and unbounded claims of Christianity, so different from the narrow sectarianism of his former religion; the accuracy with which he received into his mind, almost instantaneously, and in all their multiplicity, the mutual bearings and relations of the old economy and the new; the dauntless intrepidity with which, from the very commencement of his Christian profession, he entered into discussion with the advocates of Judaism, and vanquished them with their own weapons; the unflinching perseverance with which, in spite of danger, suffering, contumely, persecution from enemies, ingratitude and desertion from friends, he prosecuted his arduous and exhausting labours; the unwearying assiduity with which he watched over the churches of which he had the care, and the promptitude and accuracy with which he adopted and executed measures for their advantage, widely scattered and variously circumstanced though they were; the resistless force of his arguments, the persuasiveness of his appeals, the bitterness of his irony; all conspire to show that he possessed, in a high degree, those capacities for command by which men are fitted to be the leaders and directors of their fellows in enterprises of importance to the interests of the race. But it was not by attributes of strength and power alone that the mind of Paul was characterized. The sternness of these was relieved and softened by others of a more amiable and gentle cast. A vein of tenderness and sensibility flowed through his soul, which, whilst it made him the more susceptible of suffering from ingratitude or persecution, rendered him at the same time gentle and compassionate to the feelings of others. With all his freedom from Jewish prejudices, he never lost his reverence for the country and institutions of his fathers; and with all his zeal for rectitude, and all his firmness in rebuking error, he never forgot what was due to the imperfections of his brethren, or deemed that truth could be made attractive if divorced from charity. Removed alike from the extremes of fanaticism on the one hand and apathy on the other, his whole life was a noble instance of the consecration, on sound and elevated principles, of the highest powers, and the most indefatigable energies, to a work in which he had no personal interest apart from that of his fellow Christians, and from the honour which was to accrue from his exertions to that Master whom it was his high ambition to serve in life, and his animating expectation to join at death. Apart altogether from his character as an apostle of Christ, his labours in the cause of human amelioration entitle him to veneration as one of the greatest benefactors of the species; whilst in his peculiar capacity as one of the founders of the Christian church, and an inspired expositor of divine truth, he stands without a rival in his claims upon our gratitude and reverence. His history is a standing evidence of the truth of our religion; to his labours we are indebted mainly for the rapid extension of Christianity both in the East and in the West; and in his writings are contained those treasures of heavenly doctrine which it has been the chosen occupation of some of the greatest minds of subsequent ages to explore and to unfold. With these irresistible claims, the more his life, character, and writings are studied, the deeper will be the veneration in which he will be held, and the more sincere will be the gratitude of every pious mind to the Author of all good, for having, in so remarkable a manner, supplied the church with a teacher so eminently qualified to advance its best interests, and establish, to the end of time, the faith, efficiency, and enjoyment of its members. (N. N. N. N.)

Paul, *St*, an island in the South Pacific Ocean, about 10,000 toises in circumference. Long. 75. 2. E. Lat. 37. 56. S.

Paul, first bishop of Narbonne, or Sergius Paulus the proconsul, converted and made bishop by St Paul, was descended from one of the best families of Rome.

Paul, *Father*, whose name, before he entered into the monastic state, was Peter Sarpi, was born at Venice, on the 14th of August 1552. His father followed merchandise, though with so little success, that at his death he left his family very ill provided for, but under the care of a mother whose piety was likely to bring the blessing of Providence upon them, and whose wise conduct supplied the want of fortune. Happily for young Sarpi, she had a brother, master of a celebrated school, under whose direction he was placed by her; and here he lost no time, but cultivated his abilities, which were naturally of the first rate, with unwearied application. He was born for study, having a natural aversion to pleasure and gaiety, and a memory so tenacious that he could repeat thirty verses after once hearing them. Proportional to his capacity was his progress in literature. At the age of thirteen, having made himself master of school learning, he turned his attention to philosophy and the mathematics, and entered upon logic under Capella of Cremona, who, though a celebrated master of that science, confessed that in a very little time he found himself unable to give his pupil any further instructions.

As Capella was of the order of the Servites, his scholar was induced by him to engage in the same profession, although his uncle and his mother represented to him the hardships and austerities of that kind of life, and advised him with great zeal against it. But he was steady in his resolutions, and in 1566 took the habit of the order, being then only in his fourteenth year; a time of life with most persons very improper for such engagements, but in him attended with such maturity of thought, and such a settled temper, that he never seemed to regret the choice which he then made, and afterwards confirmed it by a solemn public profession in 1572.

At a general chapter of the Servites which was held at Mantua, Paul, being then only twenty years old, distinguished himself so much in a public disputation, by his genius and learning, that William duke of Mantua, a great patron of letters, solicited the consent of his superiors to retain him at his court, and not only made him public professor of divinity in the cathedral, and reader of casuistical divinity and canon law in that city, but honoured him with many proofs of his esteem. But Father Paul finding a court life not agreeable to his temper, quitted it two years afterwards, and retired to his beloved privacy, being then not only acquainted with the Latin, Greek, Hebrew, and Chaldaic languages, but with philosophy, the mathematics, canon and civil law, all parts of natural philosophy, and chemistry itself; for his application was unintermitted, his head clear, his apprehension quick, and his memory retentive.

Being made priest at twenty-two, he was by the illustrious Cardinal Borromeo honoured with his confidence, and employed by him on many occasions, not without the envy of persons of inferior merit, who were so far exasperated as to lay a charge against him before the Inquisition, for denying that the Trinity could be proved from the first chapter of Genesis; but the accusation was too ridiculous to be entertained. After this he passed successively through the dignities of his order, and having been chosen provincial for the province of Venice at the age of twenty-six, he discharged the duties of his office with such ability, that in 1579 he was appointed, with two others, to draw up new regulations and statutes for its government. This he executed with great success; and when his office of provincial expired, he retired for three years to the study of natural and experimental philosophy and anatomy, in which he is said to have made some useful discoveries. In the intervals of his employment he applied himself to his studies with an extensive capacity, which left no branch of knowledge untouched. Acquapendente, the great anatomist, confesses that he learned from Paul how vision was performed; and there are proofs that he was not a stranger to the circulation of the blood. He frequently conversed on astronomy with mathematicians, on anatomy with surgeons, on medicine with physicians, and on the analysis of metals with chemists, not as a superficial inquirer, but as a complete master. He was next chosen procurator-general of his order; and, during his residence at Rome, he was not only greatly esteemed by Pope Sixtus V., but also contracted an intimate friendship with Cardinal Bellarmine and other eminent persons.

But the hours of repose, which he employed so well, were interrupted by a new information in the Inquisition, where a former acquaintance produced a letter written by him in ciphers, in which he said, "that he detested the court of Rome, and that no preferment was obtained there but by dishonest means." This accusation, however dangerous, was passed over on account of his great reputation; but it made such an impression on that court, that he was afterwards denied a bishopric by Clement VIII. After these difficulties were surmounted, Father Paul again retired to his solitude, where he appears to have turned his attention more to improvement in piety than to learning. Such was the care with which he read the Scriptures, that, it being his custom to draw a line under any passage which he intended more nicely to consider, there was not a single word in his New Testament but was underlined. The same marks of attention appeared in his Old Testament, Psalter, and Breviary.

But the most active scene of his life commenced about the year 1615, when Paul V., exasperated by some decrees of the senate of Venice which interfered with the alleged rights of the church, laid the whole state under an interdict. The senate, filled with indignation at this treatment, forbade the bishops to receive or publish the pope's bull; and, convening the rectors of the churches, commanded them to celebrate divine service in the accustomed manner, with which most of them readily complied; but the Jesuits and some others, having refused, were by a solemn edict expelled the state. Both parties having proceeded to extremities, employed their ablest writers to defend their measures. On the pope's side, Cardinal Bellarmine entered the lists, and, with his confederate authors, defended the papal claims with great vehemence of expression, and very sophistical reasonings; which were confuted by the Venetian apologists in much more decent language, and with greater solidity of argument. On this occasion Father Paul was eminently distinguished by his Defence of the Rights of the Supreme Magistrate, and his Treatise of Excommunication, translated from Gerson, with an Apology, and other writings. For these he was cited before the Inquisition at Rome; but it may easily be imagined that he did not obey the summons.

The Venetian writers, whatever might be the abilities of their adversaries, were at least superior to them in the justice of their cause. The propositions maintained on the side of Rome were, that the pope is invested with all the authority of heaven and earth; that all princes are his vassals, and that he may annul their laws at pleasure; that kings may appeal to him, as he is temporal monarch of the whole earth; that he can discharge subjects from their oaths of allegiance, and make it their duty to take up arms against their sovereign; that he may depose kings without any fault committed by them, if the good of the church requires it; that the clergy are exempt from all tribute to kings, and are not accountable to them even in cases of high treason; that the pope cannot err; that his decisions are to be received and obeyed on pain of sin, though all the world should judge them to be false; that the pope is the vicegerent of God upon earth; and that to call his power in question is to call in question the power of God; maxims which it did not require the abilities and learning of Father Paul to prove to be false and destructive. It may easily be imagined, that such principles were quickly overthrown, and that no court but that of Rome thought it for its interest to favour them. The pope, therefore, finding his authors confuted and his cause abandoned, was willing to terminate the affair by a treaty; which, by the mediation of Henry IV. of France, was concluded upon terms very much to the honour of the Venetians. But the defenders of the Venetian rights, though comprehended in the treaty, were excluded by the Romans from the benefit of it. Some, upon various pretences, were imprisoned; others were sent to the galleys; and all were excluded from preferment. But their malice was chiefly aimed against Father Paul, who soon felt the effects of it; for, as he was going one night to his convent, about six months after the accommodation, he was attacked by five ruffians armed with stilettoes, who gave him no less than fifteen stabs, three of which wounded him in such a manner that he was left for dead. The murderers fled for refuge to the nuncio, and were afterwards received into the pope's dominions; but they were pursued by divine justice, all, except one man who died in prison, having perished by violent deaths.

This, and other attempts upon his life, obliged him to confine himself to his convent, where he engaged in writing the History of the Council of Trent; a work unequalled for the judicious disposition of the matter, and the skilful texture of the narration. It is commended by Dr Burnet as the completest model of historical writing, and celebrated by Mr Worton as equivalent to any production of antiquity; a work in which the reader finds "liberty without licentiousness, piety without hypocrisy, freedom of speech without neglect of decency, severity without rigour, and extensive learning without ostentation."

In this, and other works of less consequence, he spent the remaining part of his life, until the beginning of the year 1622, when he was seized with a cold and fever, which he neglected till it became incurable. He languished more than twelve months, which he spent almost wholly in preparation for his passage into eternity; and amongst his prayers and aspirations he was often heard to repeat, "Lord, now let thy servant depart in peace." Throughout the whole course of his illness, to the last hour of his life, he was consulted by the senate in public affairs, and returned answers in his greatest weakness with such presence of mind as could only arise from the consciousness of innocence.

On the day of his death he had the passion of our blessed Saviour read to him out of St John's Gospel, and spoke of the mercy of the Redeemer, and his confidence in his merits. As his end approached, the brethren of his convent came to pronounce the last prayers, with which he could only join in his thoughts, being able to pronounce no more than the words *Esto perpetua*, which was understood to be a prayer for the prosperity of his country. He died in the seventy-first year of his age, hated by the Romans as their most formidable enemy, honoured by all the learned for his abilities, and esteemed by the good for his integrity.

PAULEE, or Pauleegur, a celebrated fortress and town of Hindustan, province of Aurungabad, and district of Concan. It is erected on the top of an insulated mountain, about 1500 feet in height, and is inaccessible on the north side, which is well defended. It contains several reservoirs of water, and the store-rooms and other places are hewn out of the solid rock. This extraordinary fortress was taken in 1818 by the British troops. There is another town of the same name in the province of Ajmeer, and one of the greatest commercial marts in Rajpootana, where the commodities of Europe, Persia, and the Deccan are exchanged for those of Cashmere and the northern and eastern parts of Hindustan. Paulee is also the name of a town and fortress in the south of India, province of Malabar.

PAULIANISTS, Paulianistæ, a sect of heretics, so denominated from their founder Paul of Samosata, who was elected bishop of Antioch in 262. His doctrine seems to have amounted to this, that the Son and the Holy Ghost exist in God in the same manner as the faculties of reason and activity do in man; that Christ was born a mere man, but that the reason or wisdom of the Father descended into him, and by him wrought miracles upon earth, instructing the nations; and that, on account of this union of the Divine Word with the man Jesus, Christ might be called God, though, as he conceived, improperly. It is also said that he did not baptize in the name of the Son; for which reason the council of Nice ordered those who had been baptized by him to be rebaptized.

Being condemned by Dionysius Alexandrinus in a council, he abjured his errors to avoid deposition; but he soon afterwards resumed them, and was actually deposed by another council in 269. This man may be considered as the father of the modern Socinians; and his errors were severely condemned by the council of Nice. The creed agreed upon by the Nicene fathers, with a view to the errors of Paul of Samosata, concludes thus: "But those who say there was a time when he was not, and that he was not before he was born, the catholic and apostolic church anathematizes." To those who have any veneration for the council of Nice this must appear a very severe, and perhaps not unjust, censure of some other modern sects, as well as that of the Socinians.

PAULICIANS, a branch of the ancient Manicheans, so called from their founder, Paulus, an Armenian, who lived in the seventh century, and who, with his brother John, both of Samosata, formed this sect; but others are of opinion that they were so called from another Paul, an Armenian by birth, who lived under the reign of Justinian II. In the seventh century a zealot called Constantine revived this drooping sect, which had suffered much from the violence of its adversaries, and was ready to expire under the severity of the imperial edicts, and the zeal with which these were carried into execution. The Paulicians, however, by their number, and the countenance of the Emperor Nicephorus, became formidable in all the East.

But the cruel rage of persecution, which had for some years been suspended, broke forth with redoubled violence under the reigns of Michael Curopalates and Leo the Armenian, who inflicted capital punishment upon such of the Paulicians as refused to return into the bosom of the church. The Empress Theodora, tutoress of the Emperor Michael, in 845 obliged them either to recant or to quit the empire; upon which several of them were put to death, and more retired amongst the Saracens.

Upon this they entered into a league with the Saracens; and choosing as their chief an officer of the greatest resolution and valour, whose name was Carbeus, they declared against the Greeks a war which was carried on during fifty years with the greatest exasperation and fury. During these commotions, some Paulicians spread their doctrines amongst the Bulgarians; but many of them, either from a principle of zeal for the propagation of their opinions, or from a natural desire of flying from the persecution which they suffered under the Grecian yoke, retired, about the close of the eleventh century, from Bulgaria and Thrace, and formed settlements in other countries. Their first migration was into Italy; and thence, in process of time, they sent colonies into almost all the other provinces of Europe, and formed gradually a considerable number of religious assemblies, who adhered to their doctrine. In Italy they were called *Patarini*, from a certain place called Pataria, being a part of the city of Milan, where they held their assemblies; and *Gathari* or *Gazari*, from Gazaria, or the Lesser Tartary. In France they were called *Albigenses*, and anxiously concealed their more obnoxious doctrines. The first religious assembly which the Paulicians had formed in Europe is said to have been discovered at Orleans in 1017, under the reign of Robert, when many of them were condemned to be burned alive. The ancient Paulicians, according to Photius, expressed the utmost abhorrence of Manes and his doctrine; but it is nevertheless certain that their successors were Manicheans. The Greek writers comprise their errors under the six following heads. They denied that this inferior and visible world is the production of the Supreme Being, distinguishing the Creator of the world and of human bodies from the Most High God who dwells in the heavens; they treated contemptuously the Virgin Mary; they refused to celebrate the institution of the Lord's Supper; they loaded the cross of Christ with contempt and reproach; they rejected the books of the Old Testament, and looked upon the writers of that sacred history as inspired by the Creator of this world, and not by the Supreme God; and they excluded presbyters and elders from all share in the administration of the church.

PAULINUS, a bishop who flourished in the early part of the seventh century. He was the apostle of Yorkshire, and the first archbishop of York. This dignity seems to have been conferred upon him about the year 626. He built a church at Almonbury, which he dedicated to St Alban, and there he preached to and converted the Brigantes. Camden mentions a cross at Dewsborough, which had been erected to him, with this inscription, "Paulinus hic prædicavit et celebravit." About this time York was so small that there was not so much as a church in it in which King Edwin could be baptized. Constantius is said to have made it a bishopric; and Pope Honorius erected it into a metropolitan see. We are told that Paulinus baptized in the river Swale, in one day, ten thousand men, besides women and children, on the first conversion of the Saxons to Christianity. At Walstone, in Northumberland, he baptized Segbert king of the East Saxons. Bede says, "Paulinus coming with the king and queen to the royal manor called *Ad Gebdrin* (now Yeverin), staid there thirty-six days with them, employed in the duties of catechizing and baptizing. In all this time he did nothing from morning to night but instruct the people, who flocked to him from all the villages and places, in the doctrine of Christ and salvation; and, after they were instructed, he baptized them in the neighbouring river Glen." According to the same venerable author, "he preached the word in the province of Lindissi; and first converted the governor of the city of Lindocollina, whose name was Blecca, with all his family. In this city he built a stone church of exquisite workmanship, whose roof being ruined by long neglect or the violence of the enemy, only the walls are now standing." He is also said to have founded a collegiate church of prebends near Southwell, in Nottinghamshire, dedicated to the Virgin Mary. This church he is stated to have built when he baptized the Coritani in the Trent.

PAULO, Marco, a celebrated traveller, was son of Nicholas Paulo, a Venetian, who, with his brother Matthew, about the year 1255, visited Constantinople, in the reign of Baldwin II. Nicholas, at his departure, left his wife pregnant; and she brought to the world the famous Marco Paulo, the subject of this notice. The two Venetians, having taken leave of the emperor, crossed the Black Sea, and travelled into Armenia, whence they passed over land to the court of Barka, one of the greatest lords of Tartary, who loaded them with honours. This prince having been defeated by one of his neighbours, Nicholas and Matthew made the best of their way through the deserts, and arrived at the city where resided Kublai, khan of the Tartars. Kublai was entertained with the account which they gave him of the European manners and customs; and appointed them ambassadors to the pope, in order to demand of his holiness a hundred missionaries. They accordingly returned to Italy, obtained from the pontiff two Dominicans, the one an Italian and the other an Asiatic, and carried along with them young Marco, for whom Kublai expressed a singular affection. This young man, having learned the different dialects of Tartary, was employed in embassies which gave him the opportunity of traversing Tartary, China, and other eastern countries. At length, after a residence of seventeen years at the court of the khan, the three Venetians returned to their own country, in the year 1295, with immense fortunes. A short time after his return, Marco, serving his country at sea against the Genoese, lost his galley, in a great naval engagement, and was himself taken prisoner and carried to Genoa. He remained there many years in confinement; and, to amuse his melancholy as well as to gratify his friends, he sent for his notes from Venice, and composed the history of his own and his father's voyages in Italian, under this title, *Delle Maraviglie del Mondo da lui vidute;* the first edition of which appeared at Venice in 1496, in 8vo. His work was translated into different languages, and inserted in various collections. The editions most esteemed are the Latin one published by Andrew Muller at Cologne, 1671, in 4to, and that in French, to be found in the collection of voyages published by Bergeron, at the Hague, 1735, in two vols. 4to. In the writings of Marco Paulo there are some things true, and others highly incredible. It is indeed difficult to believe, that as soon as the khan was informed of the arrival of the two Venetian merchants, who were come to sell theriaca, or treacle, at his court, he sent before them an escort of forty thousand men, and afterwards despatched these Venetian ambassadors to the pope, to beseech his holiness to send him a hundred missionaries. It is equally difficult to believe that the pope, who doubtless had an ardent zeal for the propagation of the faith, should, instead of a hundred, have sent him only two missionaries. There are, therefore, some errors and exaggerations in Marco Paulo's narrative; but many other things which were afterwards verified, and which have been of no little service to succeeding travellers, prove that in several respects his relation is valuable. He not only gave better accounts of China than had before been received, but likewise furnished a description of Japan, of many of the islands of the East Indies, of Madagascar, and of the coasts of Africa; so that from his work it might be easily collected, that a direct passage by sea to the Indies was not only possible, but practicable. It may be worth while to add, that, in the opinion of the authors of the Universal History, what he wrote down from his own knowledge is both curious and true; so that where he has erred, his father and uncle must have deceived him.

PAULO, San, a large and important province of Brazil, in South America, celebrated for the courage of its inhabitants, and for the number of expeditions which have sailed from it for the purpose of exploring the interior. It is formed by the union of a part of the old capitanship of St Amaro with half of that of St Vincente, and received its present name in the year 1710, when John V., having incorporated them with the crown-lands by purchase, appointed the city of St Paulo as the residence of the captain-general. It is separated from the province of Rio de Janeiro on the north-east by a line which, traversing the heights of the vast serra from the point of Joatinga to the head of the Jacuy, descends that river till it joins the Paraiba. The Serra do Montequeira interposes between it and Minas Geraes on the north, the Rio Grande and the Parana separate it from Poyaz and Matto Grosso on the west and north-west, the Saha from St Catherina on the south, and for its eastern boundary it has the Atlantic Ocean. Its territory is almost all within the temperate zone, between 20.30. and 28.0. of south latitude, measuring 450 miles from north to south, and having a medium breadth of 340 miles. St Paulo is divided into three comarcas or ouvidorias, viz. St Paulo, Hitu, and Curytiba, each called after the principal town situated in it. Excepting on the eastern part, where a cordillera or elevated ridge of mountains runs parallel with the coast, this province is not mountainous. With the exception of Para, not one of the maritime provinces contains so many navigable rivers as St Paulo; but, unfortunately, all these flow into the interior, and are absorbed by the mighty Parana, so that they do not in any way facilitate intercourse with the coast. The few streams or mountain torrents which descend the eastern declivity of the cordillera, and fall into the Atlantic, are of no use in a commercial point of view, not being navigable. This province, like most others of Brazil, abounds in large forests, the trees being such as are common to the country. These are succeeded by plains and gently rising hills, covered with scattered bushes, and extensive tracts of verdure, which form by far the largest proportion of its surface; and hence St Paulo is pre-eminently adapted for the breeding of cattle, vast herds of which everywhere abound. Oxen, horses, and mules thrive exceedingly well, and are particularly numerous. Sheep are not attended to; but here there is a very fine and large breed of goats, whose milk is generally used. The soil of this province is in many parts very rich, and the vegetable productions are numerous and luxuriant. The articles chiefly cultivated are wheat, rye, maize, manioc, rice, and potatoes; and lately the vine has been introduced with perfect success. The palma Christi grows in such abundance that castor oil is burned in lamps instead of spermaceti. Cotton and coffee do not appear to thrive very well, and the sugar-cane but indifferently; yet rum is made in quantities sufficient to supply the home consumption of that article. Little mandioc is cultivated, but maize is raised to a great extent, and considerable quantities of it are sent to Rio. In some parts this grain, and also rice, yield two hundred and fifty fold; an extraordinary return, when we consider that in England the produce of wheat is only as twelve to one. The mulberry tree attains to great perfection in this climate, and the silk-worms are said to produce a very beautiful thread, so that the culture of silk might be carried on with great success. The cochineal insect is also found in many parts of the province, and might be made to furnish an equally profitable branch of trade. But the aversion of the Paulistas to laborious work, as long as they can obtain the rich gifts of nature without much trouble, has hitherto prevented this branch of industry from being prosecuted. The jasmine is here a favourite tree, and bears flowers perennially, as does also the rose. Bees are by no means uncommon; and although insects are numerous, the mosquito is less troublesome than in Rio or La Plata.

The bulk of the inhabitants of St Paulo are graziers, the breeding of cattle being the chief occupation. The vast grassy campos, which extend over the surface of the province, afford every facility for prosecuting it upon a great scale; and, by the following extract from the valuable work of Dr Von Spix, it will be seen that the Paulistas take every advantage of their situation. "Every landholder possesses, according to the extent of his farm, from several hundred to two thousand, nay, even forty thousand, head of cattle. They generally reckon from three to four thousand head on an estate which has two square miles of good pasture. All these roam at liberty in a wild state; but every farmer keeps, besides, as many tame draught oxen and cows as he requires for the purposes of agriculture and milk, which is partly made into cheese. The attendance on the wild cattle gives but very little trouble; all that is required is to brand them with the mark of the owner, and to catch the animals intended to be slaughtered. From four to six servants, under the direction of a chief cowherd, perform all these services; they prevent the herds from straying beyond the boundaries, and defend them from the attacks of the ounces, wolves, and wild dogs. These people are almost always on horseback, as their office compels them to ride twenty miles or more in a day. Every year the whole herd is collected at different times in a place in a high situation, and sometimes fenced in. On this occasion the mark of the owner is branded on the hind quarter of the beasts one year old, of which they reckon a thousand annually for a herd of five or six thousand. Those of four years old or more are selected for slaughter." The hide is always the most valuable part of the cattle; but the flesh also, after being salted, is exported in great quantities to the cities of the north. The breeding of horses and mules likewise occupies the attention of the farmers of St Paulo. The horses of this province are of a middling size, of slender make, and, if they are attended with care, acquire an elegant carriage, and become excellent racers. In general twenty or thirty of these wild horses herd together, and hardly ever separate. Both they and the wild cattle are captured, as in the pampas of Buenos Ayres, by long leathern nooses, which, Mr Mawe informs us, the Paulistas use with incredible dexterity. The mules here are more handsomely formed animals than the horses. They are commonly equal in size to the European horse; and their colours are black, brown, fallow, or they are striped like the zebra. They are preferable to the horses, especially on long journeys, as they can endure hunger and thirst much longer, and carry heavier burdens with much greater security.

The working of the gold and iron mines of St Paulo is the next branch of the industry of the province which requires to be noticed. The celebrated gold-mines of Jaragua are situated about twenty-four miles from the capital of the province. They were the first discovered in this country, and, on account of the immense treasures which they produced above a century ago, this district was regarded as the Pasco of Brazil. After having been abandoned for some time, the gold-washing had been resumed at the period of Dr Von Spix's visit in 1818. The mountain of Jaragua is one of the most southerly branches of the Serra do Montequeira, which, after running for more than fifty miles to the north, disappears in this latitude. The rock is granite, sometimes gneiss, containing a portion of hornblende with mica. The earth washed for gold Dr Spix describes as "a ferruginous sandstone conglomerate. The soil is red and remarkably ferruginous. The gold lies for the most part in a stratum of rounded pebbles and gravel, called cascalhao, incumbent on the solid rock. In the valleys where there is water occur frequent excavations made by the gold-washers, some of them fifty or a hundred feet wide, and eighteen or twenty feet deep. On many of the hills, where water can be collected for washing, particles of gold are found in the soil, scarcely deeper than the roots of the grass." The gold is obtained by the usual process of washing with water, negroes being chiefly employed in the operation. The pursuit of this precious metal has now much declined in St Paulo, the gold-hunters finding a richer harvest in the provinces of Minas Geraes and Matto Grosso.

In the mountain of Guarassojava, situated about twenty leagues from St Paulo, the capital city of the province, there are vast mines of magnetic ironstone; and a foundery for obtaining the metal has been erected on the banks of the Ypanema or Hipaunema, round which a small village has grown up. The mines were never regularly worked until 1810, when a company of Swedish miners were brought to the spot, and erected two small furnaces. In 1818 a handsome and extensive edifice was built, with every necessary convenience for the miners. Operations then commenced with considerable vigour; but as the wood in the neighbouring forests is the only kind of fuel of which they have any command, Dr Spix anticipates that a want of this indispensable article will by and by be experienced. The ore appears to be very rich, some of it containing ninety per cent.; and it exists in such incredible abundance, that Dr Spix thinks St Paulo might supply not only Brazil, but all the rest of the American continent, with that metal, if exportation were only facilitated by making a proper road or canal to the coast. The mountain which produces this extraordinary quantity of ore rises behind the neat little town of St João de Ypanema, a quarter of a mile to the west, and extends, as a rather insulated mountain ridge, a league in length from south to north. The mass of magnetic ironstone is either compact or traversed by veins of red ochre. The surface of the masses of rock, which rise nearly perpendicularly to the height of forty feet and more, is almost everywhere flat and even, with slight depressions and cavities, and has a crust of imperfectly oxidated ironstone. Dr Spix informs us that he did not observe that the great masses caused any motion in a suspended needle; but small pieces, especially when just struck off, had a considerable effect on it.

The city of St Paulo, from which the province derives its name, is the most ancient in Brazil, and, beyond every other, interesting in an historical point of view. "Here, more than in any other place," says Dr Spix, "we find the present connected with the past. The Paulista is sensible of this, and says, not without pride, that his native city has a history of its own." It is situated at the angle of the confluence of the Tamandatahi, which washes it on the west, with the Hynhangabahu, which flows on the eastern side. The celebrated Anchieta and his brother Jesuits commenced this city in the year 1552, with the foundation of a college, in which they celebrated the first mass on St Paul's day; and when, six years afterwards, it acquired the denomination of a town, its name was determined by this circumstance. Its first inhabitants were Indians, but they were soon joined by Europeans in great numbers, and a mixed race rapidly augmented the population; so that, before a century had elapsed, the Paulistas had become as formidable by their numbers as they were distinguished by their spirit of enterprise. Their love of travelling, and the hope of discovering the treasures of the New World, prevented them from cultivating their own fertile territory. They visited almost every part of Brazil. They crossed lofty mountains, until then deemed impassable. They were not checked by rivers, deserts, nor savage men, who waged perpetual war against them. The richest mines of Brazil were discovered by the Paulistas, who abandoned them with regret, and reluctantly submitted to the authority of their government. But this ardour of enterprise also led to serious evils. The early historians describe them as a lawless tribe, who had shaken off the yoke of Portugal, and constituted themselves a separate republic. They certainly acted in many instances in a perfectly independent manner, making incursions into the neighbouring countries, and committing the most dreadful barbarities. Paraguay suffered severely by these inroads, and the missions which had been formed in that country were at one time nearly ruined by the Paulistas. (See the article PARAGUAY.) The selfish rudeness and insensibility which formerly distinguished the Paulista is now much softened; and, although pride, revenge, and stubbornness are still recognised as forming part of his character, he enjoys throughout Brazil the reputation of great frankness, undaunted courage, and a romantic love of adventures and dangers.

The city of St Paulo is well laid out on an eminence of about two miles in extent, and rising about fifty feet above the wide plain of Pirantininga. Placed exactly at the angle formed by the confluence of the rivers Tamandatahi and Hynhangabahu, the former washes it on the western, and the latter flows past its eastern side. The streets are broad, light, and cleanly; and some of them are well paved, with a material in which particles of gold are found after a heavy rain has searched the chinks and hollows. The houses in the principal streets are two or three stories in height, stuccoed in various colours, and frequently having latticed balconies. The walls are erected by means of a framework made of wood, into which earth is put, which the workmen heat and occasionally moisten with water, until it acquires solidity. These houses of earth appear to be very durable, for Mr Mawe mentions that he saw some which had lasted two centuries. The residence of the governor, formerly the Jesuits' College, is built in a very good style, but has fallen into decay. The episcopal palace and the Carmelite convent are large and stately edifices, and the cathedral and some of the churches are spacious. The city is divided into two parishes; that of the Cathedral, and that of the Church of St Efigenia. Besides the public buildings already mentioned, St Paulo contains several chapels, monasteries, and nunneries, and three hospitals. Few manufactures of any consequence are carried on. A little coarse cotton is spun by the hand, and woven into cloth, which serves for a variety of purposes. By the most recent accounts which we have received, the manufactures are said to be improving. There is made here a beautiful kind of network for hammocks, which are fringed with lace, and form an elegant piece of furniture. The making of lace is a general employment for females, some of whom excel in it. Shopkeepers are a very numerous class here, and various trades are prosecuted with considerable spirit. A coarse earthenware is made at the outskirts of the city; but the great proportion of the inhabitants are farmers and inferior husbandmen, who cultivate small portions of land, on which they breed large stocks of pigs and poultry for sale. With these the market is generally well supplied, and also with various kinds of fruit and vegetables. St Paulo is esteemed a most healthy situation; and the climate, Dr Spix says, is one of the most agreeable in the world. Its situation, almost under the tropic of Capricorn, as well as its elevation of 1200 feet above the surface of the sea at Santos, imparts to the city all the charms of a tropical climate, without any great inconvenience from heat. The thermometer ranges from 50° to 80° of Fahrenheit. The population, including the dependent parishes, was estimated, Dr Spix says, at above 30,000 souls, of which one half were whites, or those who were reckoned such, and one half were people of colour. Henderson, in his history of Brazil, states the population as being from 35,000 to 40,000; but an official return for 1815 fixes the population of the city at 25,313 souls, of whom 12,274 were whites, 845 free blacks, 6239 free mulattoes, and 5955 slaves. The number of inhabitants must have considerably increased since the date of the above census, and, in the absence of official reports, we probably do not over-estimate the population in 1838 at 40,000. In general the principal characteristics of the Paulistas are, a lofty, and, at the same time, broad make; strongly-marked features, expressive of a bold, independent spirit; with eyes full of fire, and motions indicative of great vivacity. They are considered as the strongest, most healthy, and most active inhabitants of the country; and "the appellation of Paulista," says Mr Mawe, "is considered by all the females here as a great honour, the Paulistas being celebrated throughout Brazil for their attractions and their dignity of character." The city of St Paulo stands in lat. 23. 33. 10. south, and long. 46. 39. 10. west from Greenwich.

Santos is the only harbour in the province which has a direct intercourse with Europe; but, although no more than twelve leagues distant from the capital, the want of water communication, and the difficult nature of the road between the two cities, render the transport of goods a matter of considerable labour and expense. The road from Santos to St Paulo is cut in many places through solid rocks, and in others along the edge of precipices, which are fenced by parapets, otherwise the traveller might be in danger of falling into an impervious thicket more than thirty yards below him. Some fine springs, issuing from elevated sources, form romantic cascades in the midst of detached rocks. In these places the rocks consist of granite, and soft ferruginous sandstone, but everywhere else the mountains are covered with thick woods; even on the road branches of trees meet and form arbours, that defend the traveller from the rain, and shelter him from the heat of the sun. There are two other seaports, but they are situated at a much greater distance from St Paulo, and both are inconsiderable. The harbour of Santos has a safe entrance, and is very secure. It is a strait, having the island of St Vincente to the left, for the extent of half a mile, when it takes a different direction. Here is situated the port, which has good anchorage and regular soundings along the shore, and is the resort of many vessels trading to the Plata. Hides and tallow are the principal articles of export, and sugar, coffee, and some European articles are received in return. Its intercourse with the capital is carried on by means of mules, which come laden with the produce of the interior, and carry back salt, earthenwares, cutlery, and other goods from Europe. Santos is tolerably well built, most of the houses being of stone, and very ancient. The situation is by no means healthy, as the country around is low, woody, and frequently deluged with rain. The rice of this district, which is raised in great quantities, is esteemed the best in Brazil, and the bananas are equally celebrated. The population, consisting chiefly of merchants, shopkeepers, and artificers, amounts to about 7000. Not far to the north of Santos Bay is the fine island of St Sebastian, which is above twenty miles in length. It is very fertile, and is reputed to produce the best sugar, rum, and tobacco, as well as the finest cattle, in all Brazil. There is a town situated on it; and opposite the island, on the mainland, is St Sebastian, formerly of some note, but now reduced to 2000 or 3000 inhabitants.

Amongst the other towns of St Paulo is Sorocaba, a flourishing place, situated on a small river of the same name which flows into the Tiete, one of the tributaries of the Parana. It is a great thoroughfare and market for mules from Rio Grande do Sul; above thirty thousand of which, it is reckoned, pass through Sorocaba annually. The population may be between five and six thousand, two thirds of the whole being whites. Sorocaba is situated in the comarca of Hitu, sixty miles west from the capital. Eighteen miles to the north-west is Hitu or Ytu, the chief town of the comarca to which it gives name. It is situated at the foot of the hills, and is excessively hot in the summer months. The soil in the neighbourhood is said to be well adapted to the culture of the sugar-cane; but it does not appear that any advantage is taken of this circumstance. There are several other towns in the comarca, but none of them of any importance.

The comarca of Curutiba is situated in the southern part of the province, and is generally mountainous on the coast, but expands inland into beautiful and salubrious campos. Mr Mawe speaks of these elevated plains as the finest district in the country, and indeed one of the finest in the world, in point of climate. Its soil and air are so excellent, that olives, grapes, apples, peaches, and other fruits grow to as great maturity as in Europe, though they are here almost in a wild state. Curutiba, the principal town, is stated to have a magnificent church; all its structures are of stone or brick, and the streets are paved. The district abounds in pine forests; hence its name *curu*, pine, and *tiba*, many; and the cedar is also common in many parts. These forests abound with the mountain hog, herds of which may be met with to the number sometimes of a hundred or more.

The Curutibanos, who are very robust, are chiefly employed in breeding cattle, horses, and mules; but they also cultivate the ground. Paranagua, which, prior to the year 1812, was the seat of the provincial magistracy, like Curutiba, is built of stone, and stands on the southern bank of the river from which it derives its name, about ten miles from the sea. The other villas of this comarca are Villa Vovade St Luis, or Guaratuba, seven miles from the sea; Antonio, ten miles west of Paranagua, at the extremity of the bay of that name; Cannanca, situated upon a small island, about ten miles within the bar of the river of the same name; and several others, including Nossa Senhora dos Prazeres, the most southern town in the province, and much infested by the savages. The Indians have still some villages, in which they live in a half-civilized state, making occasional predatory attacks on the plantations and cattle of their neighbours. On the other hand, numbers have become civilized, and reside peaceably in settlements by themselves, imitating the manners and customs of the European or Creole part of the population. The only town of importance which remains to be noticed is Taubaté, a considerable place, and rivalling the capital in antiquity. It is reckoned about a hundred miles north-east from St Paulo. In former times, when the thirst for gold was at its height amongst the Paulistas, a government establishment for the refining of the metal was founded here; and the rivalry between the Taubatenos and the Paulistas of Piratininga, rose to a rancorous and implacable feud, and many sanguinary conflicts were the consequences of this enmity, traces of which are said to exist at the present day, although gold-washing is no longer pursued at Taubaté.

According to official reports, dated in 1815, the population of the whole province then amounted to 215,021 souls. By a previous census for the year 1808, the number was 200,478, which shows an increase of nearly fifteen thousand in seven years. The population in 1830 was said to be 610,000 souls. Considering the size of the province, its vegetable wealth, and the number of its inhabitants, the trade which it carries on is comparatively small, and the proportion of pecuniary wealth in it is inferior to that of the more northern provinces. The chief articles of export are sugars, rice, hides, and Peruvian bark. (R. R. R.)

PAULUS ÆMILIUS. See ÆMILIUS, PAULUS.

PAUNGAOW, a small walled town belonging to the Mahrattas, in the province of Aurungabad, eighty-eight miles south-east from Ahmednagur. Long. 76. 12. E. Lat. 18. 14. N.

PAUSANIA, in Grecian antiquity, a festival with solemn games, in which nobody contended except free-born Spartans. They were instituted in honour of Pausanias the Spartan general, under whom the Greeks overcame the Persians in the famous battle of Platæa.

PAUSANIAS, a Spartan king and general, who signalized himself at the battle of Platæa against the Persians. The Greeks, sensible of his services, rewarded his merit with a tenth of the spoils taken from the Persians. He was afterwards appointed to command the Spartan armies, and he extended his conquests in Asia; but the haughtiness of his behaviour created him many enemies; and the Athenians soon obtained a superiority in the affairs of Greece. Pausanias, dissatisfied with his countrymen, offered to betray Greece to the Persians, if he received in marriage, as the reward of his perfidy, the daughter of their king. His intrigues being discovered by the Ephori of Sparta, he fled for safety to a temple of Minerva; and as the sanctity of the place screened him from the violence of his pursuers, the sacred building was surrounded with heaps of stones, the first of which was carried there by the indignant mother of the unhappy man. He was starved to death in the temple, and died about 474 years before the Christian era.

PAUSANIAS, a very celebrated antiquary, who is believed by Fabricius to be the same mentioned by Philostratus, in his Lives of the Sophists (ii. 13), as a native of Cæsareia ad Argæum, in Cappadocia, was the disciple of Herodes Atticus, and spent the greater part of his life at Rome, where he died at an advanced age. Siebelis, however, in the preface to his valuable edition of the works of Pausanias, remarks that this supposition respecting the place of his birth does not agree with what may be inferred from his own statements. In one passage (v. 13, 4) he seems to speak of Lydia as his native province; and though he frequently alludes to Herodes Atticus, he never speaks of him as his master, which he would scarcely have failed to do if he had owed any part of his education to him. Besides, Philostratus and Suidas are both silent in respect to the work upon Grecian Antiquities which has come down to us; and such an omission is a strong proof that they were not the same individual. The exact period of his birth and death is unknown, but he was employed on a part of his work in the reign of Hadrian, who died A. D. 139, and was writing the Antiquities of Elis A. D. 174, in the fourteenth year of the reign of M. Aurelius (v. 1, 1). He must thus have been contemporary with Aulus Gellius, Ptolemy the geographer, Fronto the philosopher, Apuleius, and Lucian, though his pursuits were not likely to bring him in contact with any of them.

The work which he has left is entitled Τῆς Ἑλλαδος Πεϱιηγησις, The Description of Greece, and is divided into ten books, containing an account of the antiquities in each of the provinces of Greece, in the following order: Attica, Corinthiaca, Laconica, Messeniaca, two books entitled Eliaca, Achaïca, Arcadica, Bœotica, and Phocica. He must have examined minutely every part of these provinces; and it is observed by Sir John Hobhouse, in his Journey through Albania, "that the exact conformity of present appearances with the minute descriptions of the itinerary is no less surprising than satisfactory." He evidently took every means in his power to be accurate in his descriptions, as he constantly refers, as a corroboration of his statements, to inscriptions on ancient monuments and works of art, and to gifts dedicated in the temples of the gods. Poets and historians also furnished him with materials to illustrate the antiquities of the places he visited. He is accused, however, like the Latin historian Livy, of credulity, and of narrating many stories which have no pretension to credibility. But, aware that such an accusation might be brought against him, he states (vi. 3, 4) that he thought himself bound to give these traditions of the Greeks, though there was no reason why he should believe them. In his style he is thought to have imitated Herodotus, but it is by no means successful.

The Greek text of Pausanias was first published at Venice in 1516 by Aldus, who was assisted by Musurus; but this edition, which is in folio, is very incorrect, having been printed from a bad manuscript. That of Francfort, 1583, in folio, reprinted at Hanau in 1613, and that of Leipzig, 1696, in folio, published by Kuhn, are accompanied by the Latin translation of Amaseo, which had appeared separately, Florence, 1551, in two volumes. This version, more elegant, but less faithful, than that of Loescher, published without the Greek text, by Oporin, forms the fourth volume of the edition published at Leipzig by Facius, 1794-1797, in four volumes 8vo., the first in which an attempt was made to collate the text with the manuscripts. The edition of Schœfer, Leipzig, 1818, in three small volumes, contains only the Greek. But that of Clavier, Paris, 1814-1821, in six volumes 8vo., is preferable to both these, notwithstanding the numerous typographical errors by which it is deformed; and it is accompanied by a new French translation. It is only necessary further to indicate the Italian translation of Bonaccinoli, Mantua, 1597, in 4to; and that which appeared at Rome 1792–1793, in five volumes 4to; the English translation of Taylor, London, 1793-1794, in three volumes 8vo; and the German translation of Goldhagen, Berlin, 1798, in two volumes 8vo.

PAUSE, a stop or cessation in speaking, singing, playing, or the like. One use of pointing in grammar is to make proper pauses in certain places.

PAUW, Cornelius de, sometimes called Nicolas, a moral philosopher and historian, born at Amsterdam in 1739. He is better known as the uncle of the revolutionist Anacharsis Clootz, than by the ancestors from whom he was descended; they are, however, reported by his nephew to have distinguished themselves in the revolutions of Holland in the sixteenth century.

It appears, from the same authority, that his name was Cornelius, and not Nicolas, but that he was not related to Cornelius de Pauw, the critic and the rival of Dorville; and that it was upon the marriage of his sister to Clootz's father that he obtained, through the interest of his brother-in-law, a Catholic canonicate at Xanten, in the territory of Cleves. He was afterwards appointed reader to Frederic king of Prussia, perhaps as an advocate of the new doctrines and principles which that sovereign was disposed to patronize; but he is said to have declined the offer of the place of an academician of Berlin, and a bishopric at Breslau. His attacks on the Jesuits, whom he accused of gross misrepresentation and exaggeration in their historical and geographical memoirs, rendered him unpopular with the Catholic clergy, though his learning and talents commanded a certain portion of their respect. He was simple in his manners, and somewhat negligent of his appearance. The close of his life was embittered by a tedious and painful disease; and he died on the 7th of July 1799.

His principal publications are, 1. Recherches sur les Américains, Berlin, 1770 and 1772, in 8vo; a work intended to show the "degraded state of the savage Americans," and forming a contrast to the speculations of some contemporary writers of celebrity: 2. Défense des Recherches, Berlin, 1771, 8vo: 3. Recherches sur les Egyptiens et les Chinois, Berlin, 1774, in two vols. 8vo; Philosophical Dissertations on the Egyptians and Chinese, translated by Captain J. Thomson, London, 1795, in two vols. 8vo. The investigation was undertaken, he observes, to show that "no two nations ever resembled each other less than the Egyptians and the Chinese;" and it must be admitted that he has sufficiently established his proposition. There is, indeed, one argument that he has employed, which appears to be founded on a mistake of the Greek historians of Egypt, who have asserted that the Egyptians had long been in the use of alphabetical characters; and the want of any alphabet amongst the Chinese is stated by M. de Pauw as affording a marked distinction from the Egyptians. There is, however, scarcely a shadow of resemblance in the particular hieroglyphical characters employed by the two nations, although the general system of beginning with a representation of a visible object, and departing, more and more, by degrees, from the fidelity of the delineation, must necessarily have been common to both. But it so happens, that out of about seventy Egyptian characters, which are compared by the Jesuits and Dr Morton with the Chinese in the Philosophical Transactions for 1769, there are about twenty of which the sense has been ascertained with tolerable accuracy by Dr Young; and of these there is only one that happens to have been rightly determined by the comparison with the Chinese, excepting two or three which are obviously mere pictures, as the moon and a bow. There is also amongst the old Chinese characters a figure of a chain, which agrees remarkably in its form with the Egyptian hieroglyphic employed as a copulative conjunction; but there is a still more striking coincidence, which M. Jomard has noticed, between the Egyptian and Chinese characters for a thousand, both of which he derives from the seed-vessel of the lotus, as containing a multitude of seeds; and if the older Chinese characters be found to preserve this resemblance as perfectly as they ought to do, it must be confessed that the suspicion of a common origin will be much strengthened by the argument. Both the Egyptians and the Chinese were condemned, M. de Pauw observes, "to an eternal mediocrity;" and the weight of this observation is certainly not diminished by any thing that has been inferred from the study of the hieroglyphics of the Rosetta stone and other monuments.

There are several papers of M. de Pauw on antiquarian subjects in the Memoirs of the Society of Cassel, and in particular one on the Temple of Juno Lacinia, vol. i. 1780. Recherches sur les Grècs were published at Berlin, 1787, in two vols. 8vo; Philosophical Dissertations on the Greeks, translated by Thomson, London, 1793, in two vols. 8vo. This work is principally devoted to the Athenians, amongst whom their boasted liberty is shown to have been confined to a very small number of citizens, who tyrannized over the rest of the inhabitants of their country. The Lacedæmonians, the Ætolians, the Thessalians, and the Arcadians, are separately discussed, but considered as comparatively contemptible; the Lacedæmonians in particular, and their successors the Mainotes, are treated with great severity, as a worthless race of dishonourable vagabonds. The athletic education of the Athenians is, however, highly applauded, from a visionary theory of the importance of the physical perfection of the body to the operations of the mind. An edition of the author's three principal works appeared at Paris, in seven volumes octavo, 1795. (See Dorsch, *Chardon-Larochette*, and Clootz, *Magaz. Encycl.* 1799; An. V. vol. ii. Widdigen, *Westph. Nationalk.* 1801, p. 215; *N. Allg. T. Bibl.* lxxiv. p. 77; Denina, *Prusse Littéraire*, iii. *N. Dict. Hist.* ix. 8vo, Par. 1804; Chalmers's *Biographical Dictionary*, xxiii. 8vo, Lond. 1815.) (L. L.)

PAVAN, or Pavane, a grave dance used amongst the Spaniards, and borrowed from them, in which the performers made a kind of wheel or tail before each other, like that of *pavo*, a peacock; from which circumstance the name is derived. The pavane was formerly in great repute, and was danced by gentlemen with cap and sword, by those of the long robe in their gowns, by princes with their mantles, and by the ladies with their trains trailing on the ground. It was called the *grand ball*, from the solemnity with which it was performed.

PAVIA, a province or delegation of the Austrian territory of Milan, in Italy, bounded on the north by Milan, on the east by Lodi, on the south by Parma and Sardinia, and on the west by Sardinia. It extends over 495 square miles, comprising, besides the capital, eight market-towns, and 183 villages, with 168,500 inhabitants. It is a very level district, drained by the river Po, and by the smaller streams of the Ticino, Lambro, and Olona. It is well cultivated, and, besides the common grain, produces much rice and maize, with some silk.

Pavia, a city of the Austro-Italian dominions, the capital of the delegation of the same name. It stands on the river Ticino, over which there is a marble bridge of seven arches. It has been fortified, but is now scarcely defensible. It is the see of a bishop, and, besides the cathedral, contains eighteen churches. It has a university furnished with a library of 33,000 volumes, a botanic garden, an anatomical theatre, a laboratory, and a physical museum. The professors are thirty-three, and the pupils from seven to eight hundred. It has some trade in silk, and in the other productions of the soil in its vicinity. It contains 1830 houses, and 23,800 inhabitants. Long. 9. 4. 18. E. Lat. 45. 10. 7. N.

PAVILION, in *Architecture*, signifies a kind of turret or building, usually insulated, and contained under a single roof, sometimes square, and sometimes in form of a dome;

and it is so called from the resemblance of its roof to a tent. Pavilions are sometimes projecting pieces in the front of a building, marking the middle of it; but sometimes the pavilion flanks a corner, in which case it is called an angular pavilion. The Louvre is flanked with four pavilions. These are usually higher than the rest of the building. Pavilions built in gardens are commonly called summer-houses, pleasure-houses, and the like. Some castles or forts consist only of a single pavilion.

Pavilion, in military affairs, signifies a tent raised upon posts to lodge in during the summer time.

Pavilion is also sometimes applied to flags, colours, ensigns, standards, banners, and the like.

Pavilion, in *Heraldry*, denotes a covering in the form of a tent, which invests or wraps up the armories of different kings and sovereigns, depending only upon God and their sword. The pavilion consists of two parts; the top, which is the chapeau or coronet, and the curtain, which forms the mantle. According to the French heralds, none but sovereign princes may bear the pavilion entire and in all its parts. Those who are elective, or have any dependence, say the heralds, must take off the head, and retain nothing but the curtains.

Pavilions, amongst jewellers, are the under-sides and corners of the brilliants, lying between the girdle and the collet.

PAVING, the construction of ground-floors, streets, or highways, in such a manner that they may be conveniently walked upon. In Great Britain the pavement of the streets and roads usually consists of flint or rubble-stone; but courts, stables, kitchens, halls, churches, and the like, are paved with tiles, bricks, flags, or fire-stone, and sometimes with a kind of freestone or ragstone.

Pavements of churches frequently consist of stones of several colours, but chiefly black and white, and of several forms, but chiefly squares and lozenges, artfully disposed. Indeed there needs no great variety of colours to produce a surprising diversity of figures and arrangements. M. Truchet, in the Memoirs of the French Academy, has shown by the rules of combination, that two square stones, divided diagonally into two colours, may be joined together chequerwise in sixty-four different ways; which appears surprising enough, since two letters or figures can only be combined two ways. The reason is, that letters only change their situation with regard to the first and second, the top and bottom remaining the same; but in the arrangement of these stones, each admits of four several situations, in every one of which the other square may be changed sixteen times, which gives sixty-four combinations. Indeed, from a further examination of these sixty-four combinations, he found that there were only thirty-two different figures, each figure being repeated twice in the same situation, though in a different combination, so that the two differed from each other only in the transposition of the dark and the light parts.

PAVO, in *Astronomy*, a constellation in the southern hemisphere, unknown to the ancients, and not visible in our latitude.

PAVOR, a Roman deity, whose worship was introduced by Tullus Hostilius. The latter, in a panic, vowed a shrine to him and one to Pallor, *Paleness;* and therefore both are found on the coins of that family.

PAW, in the manège. A horse is said to paw the ground, when, his leg being either tired or painful, he does not rest it upon the ground, and fears to hurt himself as he walks.

PAWANGHUR, a fortified town of Hindustan, in the Mahratta territories, province of Bejapoor, and district of Parnella, of which it is the capital. It is considered as a place of great strength, and is forty-two miles south by west from Merritch. Long. 74. 20. E. Lat. 16. 52. N.

PAWN, a pledge or gage for surety or payment of money lent. It is said to be derived *a pugno, quia res quæ pignori dantur, pugno vel manu traduntur;* which is certainly a far-fetched etymology. See Broker.

PAZ, La, the name of a department, a province, and a large city of Bolivia, in South America. A general account of the department, with the number of its inhabitants, will be found in the article Bolivia. The province of La Paz is a district surrounding the city of the same name, in the vicinity of the western cordillera of the Andes, and at a considerable elevation above the level of the sea. This territory is rough and uneven, but fruitful in barley, cocoa, papas, and fruits of various kinds. Its appearance has been described by Mr Temple. "In casting a glance farther round," says he, "you perceive squares and patches of every shade of green and yellow, which, to a European, is perhaps the most striking part of the interesting scene. Corn, and fruit, and vegetables, and crops of every kind, may be seen in all their stages, from the act of sowing to that of gathering them in. Here a field of barley luxuriantly green; there another in full maturity, which the Indians are busily reaping; next to it a crop just appearing above the ground; further on another arrived at half its growth; beyond it a man guiding a pair of oxen, yoked to a shapeless stick, the point of which scratches the earth sufficiently for the reception of the seed, which another man is scattering in the furrows; trees bearing fruit, and at the same time putting forth buds and blossoms, complete the scene of luxuriance. Yet it requires only to raise the eyes from the lap of this fruitful Eden, to behold the widest contrast in the realms of nature. Naked and arid rocks rise in mural precipices around. High above these, mountains, beaten by furious tempests, frown in all the bleakness of sterility; higher still, the tops of others, reposing in the region of eternal snow, glisten uninfluenced in the presence of a tropical sun." The mountains here mentioned are the Nevada de Illimani and others, situated to the south of La Paz. "Illimani, or Yllimani," says Mr Pentland, "appears to derive its name from its icy covering, *Illi*, in the Ymarra dialect of the aborigines, signifying snow. The Nevada of Illimani is situated in latitude 16. 40. Its form is that of a serrated ridge, elongated in the direction of the axis of the chain upon which it rises, offering four principal peaks to the observer, when seen from its western side. From the city of La Paz (latitude 16. 30.), distant about thirty miles, it presents itself with the imposing grandeur of Mont Blanc, when seen from Salanches, or of Monte Rosa, from the subjacent valley of Macugnaga. The elevation of this giant of the Bolivian Cordillera is 24,200 feet, and the lowest glaciers on its northern declivity do not descend below 16,500." This is the highest mountain in the New World, with the exception of the Nevada de Sorata, the highest peak of which attains an elevation of 25,250 feet above the level of the sea.

La Paz, the largest city in the republic of Bolivia, is situated in a deep valley, penetrated by the mountain torrent of Choqueapo. It was founded in the year 1548, and has a fine cathedral, several churches and convents, a college, an hospital, and numerous warehouses for the reception of goods. La Paz is the great emporium of Upper Peru, all merchandize from the coast of the Pacific being transported thither, and then conveyed, by merchants and other dealers, to the towns and villages of the interior. In the seventeenth century, about a league from this city, a large mass of solid gold was found by an Indian, and purchased for about eleven thousand dollars, by the Spanish viceroy, who sent it to the cabinet of natural history at Madrid. Large quantities of native gold have also been found from time to time at the base of the Illimani, in a lake situated at the enormous elevation of 15,780 feet above the level of the sea. This lake is celebrated as having been the depository of a great part of the treasures of the once famed city of Cuzco; for, according to tradition, the Indians chose rather to bury their wealth beneath the waters, than resign it to the rapacity of the invaders. The city of La Paz, although elevated 12,195 feet above the level of the sea, yet, from its sheltered situation, enjoys a mild and pleasant climate. The population amounts to about 40,000.

PEACE, Temple of, a very celebrated fane at Rome, which in the year 191 was consumed by a fire, produced, as some writers suppose, by a slight earthquake. Dio Cassius, however, supposes that the fire began in the adjoining houses; but however this may have been, the temple, with all the surrounding buildings, was reduced to ashes. That magnificent structure had been raised by Vespasian after the destruction of Jerusalem, and enriched with the spoils and ornaments of the temple of the Jews. The ancients speak of it as one of the most stately buildings in Rome. There men of learning used to hold their assemblies, and to deposit their writings, as many others deposited their jewels, and whatever else they esteemed of great value. It was likewise employed as a kind of magazine for the spices which were brought by the Roman merchants from Egypt and Arabia; so that many rich persons were reduced to beggary, all their valuable effects and treasures having been consumed in the conflagration.

PEAK of Derbyshire, a chain of high mountains in the county of Derby, in England, famous for the mines they contain, and also for their remarkable caverns. See Derbyshire.

PEARCE, Dr, lord bishop of Rochester, was the son of a distiller in High Holborn. He received his education in Westminster school, where he was distinguished by his merit, and elected one of the king's scholars. In 1710, when he was twenty years old, he was elected to Trinity College, Cambridge. During the first years of his residence at the university, he occasionally amused himself with lighter compositions, some of which are inserted in the Guardian and Spectator. In 1716, he published his edition of Cicero *De Oratore*, and, at the desire of a friend, dedicated it to Lord Chief Justice Parker, afterwards Earl of Macclesfield, to whom he was an entire stranger. This incident laid the foundation of his future fortune; for Lord Parker soon recommended him to Dr Bentley, master of Trinity, to be made one of the fellows; and the doctor consented to this upon condition that his lordship would promise to "unmake" him again as soon as it lay in his power to give him a living. In 1717, Mr Pearce was ordained at the age of twenty-seven, having taken time enough, as he thought, to attain a sufficient knowledge of the sacred office. In 1718, Lord Parker was appointed chancellor, and invited Mr Pearce to live with him in the capacity of his chaplain. In 1719, the latter was instituted into the rectory of Stapleford Abbots, in Essex; and, in 1720, into that of St Bartholomew, behind the Royal Exchange, worth L.400 a year. In 1723, the lord chancellor presented him to St Martin's-in-the-Fields. His majesty, who was then at Hanover, had been applied to in favour of Dr Claget, who was then along with him, and the doctor actually kissed hands upon the occasion; but, upon the king's return, the chancellor disputed the point, and was permitted to present Mr Pearce. The latter soon attracted the notice and esteem of persons in the highest stations and of the greatest abilities. Besides Lord Parker, he could reckon amongst his patrons or friends, Mr Pulteney, afterwards Earl of Bath, Archbishop Potter, Lord Hardwicke, Sir Isaac Newton, and many other eminent personages. In 1724, the degree of doctor of divinity was conferred on him by Archbishop Wake. The same year he dedicated to his patron the Earl of Macclesfield his edition of Longinus on the Sublime, with a new Latin version and notes.

When the church of St Martin's was rebuilt, Dr Pearce preached a sermon at the consecration, which he afterwards printed, and accompanied with an essay on the origin and progress of temples, traced from the rude stones which were first used for altars to the noble structure of Solomon, which he considers as the first temple completely covered. His observations on the building called the Temple of Dagon removes part of the difficulty which presents itself in the narration of the manner in which Samson destroyed it.

The deanery of Winchester having become vacant, Dr Pearce was appointed to it in 1739; and in the year 1744 he was elected prolocutor of the Lower House of Convocation for the province of Canterbury. His friends now began to think of him for the episcopal dignity; but he appeared rather to decline it. However, after several difficulties had been started and removed, he consented to accept the bishopric of Bangor, and promised Lord Hardwicke to do it with a good grace. He accordingly made proper acknowledgements of the royal goodness, and was consecrated on the 12th of February 1748. Upon the declining state of health of Dr Wilcocks, bishop of Rochester, the bishop of Bangor was several times applied to by Archbishop Herring to accept of Rochester, and the deanery of Westminster, in exchange for Bangor; but he then for the first time signified his desire to obtain leave to resign and retire to a private life. His lordship, however, upon being pressed, suffered himself to be prevailed upon. "My Lord," said he to the Duke of Newcastle, "your grace offers these dignities to me in so generous and friendly a manner, that I promise you to accept them." Upon the death of Bishop Wilcocks he was accordingly promoted to the see of Rochester and deanery of Westminster in 1756. Bishop Sherlock died in 1761, and Lord Bath offered his interest to get the Bishop of Rochester appointed to succeed him in the diocese of London; but the latter told his lordship, that he had determined never to be Bishop of London or Archbishop of Canterbury.

In the year 1763, his lordship being then in the seventy-third year of his age, and finding himself less fit for the business of his stations as bishop and dean, informed his friend Lord Bath of his intention to resign both, and live in a retired manner upon his private fortune. Lord Bath undertook to acquaint his majesty, who named a day and hour, when the bishop was admitted alone into the closet. He told the king, that he wished to have some interval between the fatigues of business and eternity; and desired his majesty to consult proper persons about the propriety and legality of his resignation. In about two months the king informed him that Lord Mansfield saw no objection, and that Lord Northington, who had been doubtful, on further consideration thought that the request might be complied with. Unfortunately for the bishop, Lord Bath had applied for Bishop Newton to succeed him. This alarmed the ministry, who thought that no dignities should be obtained except through their hands. They therefore opposed the resignation; and his majesty was informed that the bishops disliked the design. His majesty sent to him again, and at a third audience told him that he must think no more of resigning. The bishop replied, "Sire, I am all duty and submission;" and then retired. In 1768 he obtained leave to resign the deanery; in 1773 he lost his lady; and after some months of lingering decay he died at Little Ealing, on the 29th of June 1774.

This eminent prelate distinguished himself in every part of his life by the virtues proper to his station. His Literary abilities, and application to sacred and philological learning, appear by his works, the principal of which are, 1. A Letter to the Clergy of the Church of England, on occasion of the Bishop of Rochester's commitment to the Tower, 1722; 2. Miracles of Jesus vindicated, 1727 and 1728; 3. A Review of the Text of Milton, 1733; 4. Two Letters against Dr Middleton, occasioned by the doctor's letter to Waterland, on the publication of his Treatise entitled *Scripture Vindicated*, 1752; and, 5. a Commentary, with notes, on the four Evangelists and the Acts of the Apostles, together with a new translation of St Paul's first Epistle to the Corinthians, and a paraphrase, with notes, in two vols. 4to.

PEARL, in *Natural History*, a hard, white, shining body, usually roundish, found in a testaceous fish, a species of *Mya*. Pearls, though esteemed of the number of gems, and highly valued in all ages, proceed only from a distemper in the animal which produces them, analogous to the bezoars and other stony concretions in several animals of different kinds. Mr Bruce mentions muscles found in the salt springs of the Nubian desert, in many of which he observed those excrescences which might be called pearls, but all of them ill formed, foul, and of a bad colour, though of the same consistence, and lodged in the same part of the body, as those of the sea. "The muscle," says he, "is in every respect similar, I think larger. The outer skin or covering of it is of a vivid green. Upon removing this, which is the epidermis, what next appears is a beautiful pink without gloss, and seemingly of a calcareous nature. Below this, the mother-of-pearl, which is undermost, is a white without lustre, partaking much of the blue and very little of the red; and this is all the difference I observed between it and the pearl-bearing muscle of the Red Sea."

In Scotland, especially to the northward, in all rivers running from lakes, there are found muscles which have pearls of more than ordinary merit, though seldom of large size. They were formerly tolerably cheap, but the wearing of real pearls having come into fashion, those of Scotland have increased in price greatly beyond their value, and superior often to the price of oriental ones when bought in the East. The reason of this is a demand from London, where they are actually employed in work, and sold as oriental. But the excellency of all glass or paste manufactory, it is likely, will keep the price of this article, and the demand for it, within bounds, when every lady has it in her power to wear in her ears, for the price of sixpence, a pearl as beautiful in colour, more elegant in form, lighter and easier to carry, and as much bigger as she pleases, than the famous ones of Cleopatra and Servilla. In Scotland, as well as in the East, the smooth and perfect shell rarely produces a pearl; the crooked and distorted shell seldom wants one.

Artificial PEARLS. There are methods of making artificial pearls, in such manner as to be with difficulty distinguished from the best oriental. The ingredient used for this purpose was long kept a secret; but it is now discovered to be a fine silver-like substance found upon the under side of the scales of the blay or bleak fish. The scales, taken off in the usual manner, are washed and rubbed with fresh parcels of water, and the several liquors suffered to settle; after which the water being poured off, the pearly matter, of the consistence of oil, remains at the bottom, and is called by the French *essence d'orient*. A little of this is dropped into a hollow bead of bluish glass, and shaken about so as to line the internal surface; after which the cavity is filled up with wax, to give solidity and weight. Pearls made in this manner are distinguishable from the natural only by their having fewer blemishes.

*Mother-of-*PEARL, the shell, not of the pearl oyster, but of the *mytilus margaritiferus*.

PEARL-*Ash*, a fixed alkaline salt, prepared chiefly in Germany, Russia, and Poland, by melting the salts out of the ashes of burned wood, and, having reduced them to dryness, evaporating the moisture, and, calcining them for a considerable time in a furnace moderately heated. The goodness of pearl-ashes may be ascertained by a uniform and white appearance; but they are nevertheless subject to a common adulteration, not easily distinguishable by the mere appearance, and which is done by the addition of common salt. Pearl-ashes are much used in the manufacture of glass, and need no preparation, except where very great transparency is required.

PEARSON, JOHN, a learned English bishop, was born at Snoring in 1613. After his education at Eton and Cambridge, he entered into holy orders in 1639, and was the same year collated to the prebend of Netherhaven, in the church of Sarum. In 1640 he was appointed chaplain to the lord-keeper Finch, and by him presented to the living of Torrington in Suffolk. In 1650 he was made minister of St Clement's, East-Cheap, in London. In 1657, he and Mr Gunning had a dispute with two Roman Catholics upon the subject of schism, a very unfair account of which was printed at Paris in 1658. Some time afterwards he published at London an Exposition of the Creed, in folio, dedicated to his parishioners of St Clement's, East-Cheap, to whom the substance of that excellent work had been preached several years before, and by whom he had been desired to make it public. The same year he likewise published the Golden Remains of Mr John Hales of Eton; to which he prefixed a preface, containing a character of that great man, with whom he had been acquainted for many years, drawn up with great elegance and force. Soon after the Restoration, he was presented by Juxon, then bishop of London, to the rectory of St Christopher's in that city; created doctor of divinity at Cambridge, in pursuance of the king's letters mandatory; installed prebendary of Ely, archdeacon of Surrey, and made master of Jesus College in Cambridge, all before the end of the year 1668. On the 25th of March 1661, he was appointed Margaret professor of divinity in that university; and, on the first day of the ensuing year, he was nominated one of the commissioners for the review of the liturgy in the conference held at the Savoy. On the 14th of April 1662, he was admitted master of Trinity College in Cambridge; and, in August, resigned his rectory of St Christopher's and his prebend of Sarum. In 1667 he was admitted a Fellow of the Royal Society. In 1672 he published at Cambridge, Vindiciæ Epistolarum S. Ignatii, in 4to, in answer to M. Daillé; to which is subjoined, Isaaci Vossii Epistolæ Duæ adversus Davidem Blondellum. Upon the death of the celebrated Dr Wilkins, Pearson was appointed his successor in the see of Chester, to which he was consecrated on the 9th of February 1672–1673. In 1682, his Annales Cyprianici, sive tredecim annorum, quibus S. Cyprianus inter Christianos versatus est, Historia Chronologica, was published at Oxford, with Fell's edition of that father's works. Pearson was disabled from all public service by ill health a considerable time before his death, which happened at Chester, on the 16th of July 1686.

PEASANT, a hind, one whose business consists exclusively in rural labour.

PEAT, a well-known inflammable substance, employed in many parts of the world as fuel. There are two species of peat.

The first is a yellowish-brown or black peat, found in moorish grounds in Scotland, Holland, and Germany. When fresh, it is of a viscid consistence, but hardens by exposure to the air. It consists, according to Kirwan, of clay mixed with calcareous earth and pyrites; sometimes also it contains common salt. Whilst soft, it is formed into oblong pieces for fuel, after the pyritaceous and stony matters are separated from it. By distillation it yields water, acid, oil, and volatile alkali, the ashes containing a small proportion of fixed alkali, and being either white or red, according to the proportion of pyrites contained in the substance. The oil which is obtained from peat has a very pungent taste, and an empyreumatic smell, less fetid than that of animal substances, but more so than that of mineral bitumens. It congeals in the cold into a pitchy mass, which liquefies in a small heat; it readily catches fire from a candle, but burns less vehemently than other oils, and immediately goes out upon removing the external flame; and in rectified spirit of wine it dissolves almost totally into a dark brownish-red liquor.

The second species is found near Newbury in Berkshire. In the Philosophical Transactions for the year 1757, we have an account of this species, the substance of which is as follows: Peat is a composition of the branches, twigs, leaves, and roots of trees, with grass, straw, plants, and weeds, which, having lain long in water, is formed into a mass soft enough to be cut through with a sharp spade. The colour is a blackish brown, and it is used in many places for fuel. There is a stratum of this peat on each side of the Kennet, near Newbury in Berks, which is from about a quarter to half a mile in width, and many miles in length. The depth below the surface of the ground is from one foot to eight. Great numbers of entire trees are found lying irregularly in the true peat. These are chiefly oaks, alders, willows, and firs, and appear to have been torn up by the roots; many horses' heads, and bones of several kinds of deer, the horns of the antelope, the heads and tusks of boars, and the heads of beavers, are also found embedded in it.

PEBAS, a district of Peru, in South America, situated upon the left bank of the river Marañon, to the east of the confluence of the Ucayale with that river. It produces cocoa, sarsaparilla, vanilla, white and black bees-wax, maize, yucas, plantains, camotas, and papayas, and some dye-stuffs of a peculiar description. The river here supplies vaca marina, tartaruga, gavitanas, sungarros, and pacos. In the woods there are tigers, tapirs, deer, roonsookas, and black and white monkeys. The pueblo or town of Pebas is situated on a height, upon an elevated part of the bank of the river. It is built without any regard to regularity, and is chiefly inhabited by Indians, who are a cheerful and industrious race of people.

PEBBLES, a trivial name frequently given to different varieties of the agate and calcedony.

PECK, Francis, a laborious and learned antiquary, was born at Stamford, in Lincolnshire, on the 4th of May 1692, and educated at Cambridge, where he took the degrees of bachelor and master of arts. He was the author of many works, the first of which is a poem entitled Sighs on the Death of Queen Anne, printed probably about the time of her death in 1714. Two years afterwards he printed an Exercise on the Creation, and a Hymn to the Creator of the World, being an attempt to show the beauty and sublimity of the Holy Scriptures, 1716, 8vo. In 1721, being then curate of King's Clifton in Northamptonshire, he issued proposals for printing the History and Antiquities of his native town, a work which was published in 1727, in folio, under the title of Academia tertia Anglicana, or the Antiquarian Annals of Stamford, in Lincoln, Rutland, and Northamptonshires, inscribed to John duke of Rutland. This work was hastened by an Essay on the Ancient and Present State of Stamford, 1726, in 4to, written by Francis Hargrave, who, in his preface, mentions the difference which had arisen between him and Mr Peck, on account of his publication having forestalled that intended by the latter. Mr Peck is also very roughly treated on account of a small work which he had formerly printed, entitled the History of the Stamford Bull-running. Mr Peck had before this time obtained the rectory of Godeby, near Melton, in Leicestershire, the only preferment he ever enjoyed. In 1729, he printed, on a single sheet, Queries concerning the Natural History and Antiquities of Leicestershire and Rutland, which were afterwards reprinted in 1740; but although the progress he had made in the work was considerable, yet it never made its appearance. In 1732 he published the first volume of Desiderata Curiosa, or a Collection of various scarce and curious Pieces relating chiefly to Matters of English History. This volume was dedicated to Lord William Manners, and was followed, in 1735, by a second volume, dedicated to Dr Reynolds, bishop of Lincoln. In the year 1735 Mr Peck printed a complete catalogue of all the discourses written for and against Popery in the time of King James II., containing in the whole an account of 457 books and pamphlets, a great number of them not mentioned in the three former catalogues; with references after each title, for the more speedily finding a further account of the said discourses and their authors in sundry writers, and an alphabetical list of the writers on each side. In 1739 he edited Nineteen Letters of the Reverend Dr Henry Hammond, author of the Annotations on the New Testament, written to Mr Peter Stainnough and Dr Nathaniel Angelo, many of them on curious subjects. These were printed from the originals, communicated by Mr Robert Marsden, archdeacon of Nottingham, and Mr John Worthington. The next year, 1740, he produced two volumes in quarto, one of them entitled Memoirs of the Life and Actions of Oliver Cromwell, as delivered in three panegyrics of Noll, written in Latin, and supposed to have been composed by John Milton, Latin secretary to Cromwell. The other contained New Memoirs of the Life and Poetical Works of Mr John Milton, with an examination of Milton's style, and explanatory and critical notes on different passages in Milton and Shakspeare, by the editor; besides a variety of other pieces, which it would be tedious to enumerate. These were the last publications which he gave the world. When they appeared, however, he had in contemplation no less than nine different works; but, from some cause not explained, none of them was ever made public. He concluded a laborious, and, it may be added, useful life, wholly devoted to antiquarian pursuits, on the 13th of August 1643, at the age of sixty-one years.

PECS, a city of the Austrian kingdom of Hungary, in the province of the Hither Danube, and circle of Baranyer. It is situated on a river of the same name, upon whose banks it extends in a single street more than six miles in length. It is the see of a bishop, the seat of a Catholic seminary, and contains convents and hospitals, with 2160 houses, and 9640 inhabitants, who produce vinegar, tobacco, starch, and some good wine. It has also much trade, arising from several great fairs for cattle and leather, which are held there. Long. 18. 10. E. Lat. 46. 5. 13. N.

PECTORAL, a sacerdotal habit or vestment, which was worn by the Jewish high priest. The Jews call it *Hhoschen*, the Greeks γολιον, the Latins *rationale* and *pectorale*, and in our version of the Bible it is called *breastplate*. It consisted of embroidered stuff, about a span square, and was worn upon the breast, set with twelve precious stones, arranged in four rows, and containing the names of the twelve tribes. It was fastened to the shoulder by two chains and hooks of gold. God himself prescribed the form of the pectoral.

Pectoral, a breastplate of thin brass, about twelve fingers square, worn by the poorer soldiers in the Roman army, who were rated under one thousand drachmæ.

PECULIAR, in the *Canon Law*, signifies a particular parish or church that has jurisdiction within itself for granting probates of wills and administrations, exempt from the ordinary or bishop's courts. The king's chapel is a royal peculiar, exempt from all spiritual jurisdiction, and reserved to the visitation and immediate government of the king himself. There is likewise the archbishop's peculiar; for it is an ancient privilege of the see of Canterbury, that wherever any manors or advowsons belong to it, these forthwith become exempt from the ordinary, and are reputed peculiars. In the see of Canterbury there are fifty-seven such peculiars.

Besides these, there are some peculiars belonging to deans, chapters, and prebendaries, which are only exempted from the jurisdiction of the archdeacon. They are derived from the bishop, who may visit them, and to whom there lies an appeal.

Court of Peculiars is a branch of, and annexed to, the court of arches. It has a jurisdiction over all those parishes dispersed throughout the province of Canterbury in the midst of other dioceses, which are exempted from the ordinary's jurisdiction, and subject only to the metropolitan.

PECULIUM signifies the stock or estate which a person in the power of another, whether male or female, either as his or her slave, may acquire by his industry. Roman slaves frequently amassed considerable sums in this way. The word properly signifies the advanced price which a slave could get for his master's cattle or stock above the price fixed upon them by his master, and which was the slave's own property.

In the Catholic church, *peculium* denotes the goods which each religious reserves to and possesses by himself.

PEDAGOGUE, or PÆDAGOGUE, a tutor or master, to whom is committed the discipline and direction of a scholar, to be instructed in grammar and other arts. The word is formed from the Greek παιδων ἀγωγος, *puerorum ductor*, or leader of boys.

PEDAL (*pedale* in Italian), is a musical term of various meanings. For example, *pedal* means one of the largest pipes, or one of the foot-keys, of an organ; or the foot-piece attached to a piano-forte, a harp, or the like, and by which, in the former, the intensity of the sound is modified, and, in the latter, the chromatic changes of intonation are produced. It also signifies a particular sort of passage in the course of a piece of music, where the harmony moves upon a sustained sound, which is either the dominant or the tonic of the key. (See the article MUSIC, vol. xv. p. 640.)

PEDANT, a schoolmaster or pedagogue, who professes to instruct and govern youth, and to teach them the languages and the arts.

PEDANT is also used for a rough, unpolished man of letters, who makes an impertinent use of the sciences, and abounds in unseasonable criticisms and observations.

PEDARIAN, in Roman antiquity, were those senators who signified their votes by their feet, not with their tongues; that is, such as walked over to the side of those whose opinion they approved of, in divisions of the senate. Dr Middleton thus accounts for the origin of the word. He says, that though the magistrates of Rome had a right to a place and vote in the senate both during their office and after it, and before they were put upon the roll by the censors, yet they had not probably a right to speak or debate there upon any question, at least in the earlier ages of the republic. For this seems to have been the original distinction between them and the ancient senators, as is plainly intimated in the formula of the consular edict, sent abroad to summon the senate, which was addressed to all senators, and to all those who had a right to vote in the senate. From this distinction, those who had only a right to vote were called in derision *pedarian;* because they signified their votes by their feet, not their tongues, and upon every division of the senate went over to the side of those whose opinion they approved. It was in allusion to this ancient custom, which seems to have been wholly dropped in the latter ages of the republic, that the mute part of the senate continued still to be called by the name of *pedarians;* as Cicero informs us, who, in giving an account to Atticus of a certain debate and decree of the senate upon it, says that it was made with the eager and general concurrence of the pedarians, although against the authority of all the consulars.

PEDATURA, a term used in Roman antiquities to indicate a space or proportion of a certain number of feet set apart. This word often occurs in writers on military affairs. In Hyginus *De Castrametatione* we meet with the following passage, viz. "Meminerimus itaque ad computationem cohortis equitatæ milliariæ pedaturam ad mille trecentos sexaginta dari debere;" the meaning of which is, that *pedatura*, or space allowed for a *cohors equitata* or provincial cohort, consisting of both horse and foot, could not be the same as the *pedatura* of an uniform body of infantry, of the same number, but must exceed it by 360 feet; for the proportion of the room occupied by one horseman to that occupied by one foot soldier was estimated as two and a half to one.

PEDDABALABARAM, a town of Hindustan, in the Mysore rajah's territories. The fort is built entirely of mud, but it is nevertheless large and strong; and one side is surrounded by gardens, the other by the town. Its trade is inconsiderable. Long. 77. 47. E. Lat. 13. 17. N.

PEDDAPORE, a town of Hindustan, in the Northern Circars, and district of Rajamundry, twenty-five miles east-north-east from the town of Rajamundry. Sugar is cultivated in the neighbourhood to a considerable extent. A battle was fought here in 1758, between the French and English, in which the former were totally defeated. Long. 82. 15. E. Lat. 17. 5. N.

PEDESTAL, in *Architecture*, the lowest part of an order of columns, being that part which sustains the column, and serves it as its base.

PEDIÆAN, in Grecian antiquity. The city of Athens was anciently divided into three different parts; one on the descent of a hill, another on the sea-shore, and a third in a plain between the other two. The inhabitants of the middle region were called Πεδιαιοι, *Pediæans*, from πεδιον, plain or flat; those of the hill, Diacrians; and those of the shore, Paralians. These quarters usually composed as many different factions. Pisistratus made use of the Pediæans against the Diacrians. In the time of Solon, when a form of government was to be chosen, the Diacrians chose the democratic, the Pediæans demanded an aristocracy, and the Paralians a mixed government.

PEDICLE, amongst botanists, that part of a stalk which immediately sustains the leaf of a flower or a fruit, and is commonly called a *footstalk*.

PEDIR, a town on the western coast of the island of Sumatra, from which are exported betel-nut, pepper, gold dust, canes, rattans, bees-wax, camphor, and benzoin or frankincense. The soil around is fertile, and the country well watered.

PEDOMETER, or PODOMETER, formed from πους, *pes*, foot, and μετρον, measure, a mechanical instrument, in the form of a watch, consisting of various wheels with teeth, catching in one another, all disposed in the same plane, which, by means of a chain or string fastened to a man's foot, or to the wheel of a chariot, advance a notch each step, or each revolution of the wheel; so that the number being marked on the edge of each wheel, one may number the paces, or measure exactly the distance from one place to another. There are some of them which mark the time on a dial-plate, and, being very much like a watch, are accordingly worn in the pocket.

PEDRA BLANCA, a large and elevated rock, perfectly white, and situated in the Sea of China. Long. 114. 57. E. Lat. 22. 19. N.

PEDRO, DOM, of Portugal, Duke of Coimbra, was the fourth child and second surviving son of King John of Portugal, and was born on the 4th of March 1394. His father gave him an excellent education, which, joined to strong natural abilities and much application, rendered him one of the most accomplished princes of his time. He was not only very learned himself, but a great lover of learning, and also a patron of learned men. It was chiefly with a view to improve his knowledge that he spent four years in travelling throughout different countries in Europe, Asia, and Africa, with a train suitable to his quality. There is a relation of these travels still extant, but so loaded with fabulous circumstances, that it wounds the reputation it was designed to raise. At his return he espoused Isabella, daughter to the Count of Urgel, and grand-daughter to Dom Pedro, the fourth king of Portugal; which was esteemed a very great advancement of his fortune. He was elected a member of the most noble order of the Garter on the 22d of April 1417, in the fifth year of the reign of his cousin Henry V. a grandson of John of Gaunt by the father's side, as our Duke of Coimbra was by the mother. In 1440 he was declared regent during the minority of his cousin Dom Alonzo V. son of King Edward, who died of the plague. He found some difficulty at first in the discharge of his office, both from the queen-mother and others. But, upon the whole, his administration was so mild and so just, that the magistrates and the people of Lisbon concurred in demanding permission to erect a statue to him. The regent thanked them, said he should be unwilling to see a work of theirs demolished, and that he was sufficiently rewarded by this public testimony of their affections. The queen dowager wished to raise disturbances in Portugal, by aiming at recovering the regency to herself; but the steadiness of the regent's administration, the attachment of the greater part of the nobility to him, and his enjoying in so absolute a degree the confidence of the people, not only secured the interior tranquillity of the state, but likewise raised the credit of the crown of Portugal to a very great height in the estimation of its neighbours. In the course of his regency he had made it his continual study to pursue the public good; to ease the people in general, and the inhabitants of Lisbon in particular, of several impositions; to maintain the laws in their full vigour; to give the king an excellent education; and, if that had been at all practicable, to diffuse a perfect unanimity throughout the court, by assuaging the malice and envy of his enemies. The king, when he came of age, and the *cortes* or parliament, expressed their entire satisfaction with the regent's administration; and all parties entirely approved of the king's marriage with Donna Isabella, the regent's daughter, which was celebrated in 1446. The enmity of his enemies, however, was not in the least abated by the regent's being out of office. They still persecuted him with their unjust calumnies, and unfortunately induced the king to hearken to their falsehoods. The unfortunate duke, when ordered to appear before the king, was advised to take with him an escort of horse and foot. In his passage he was proclaimed a rebel, and almost immediately surrounded by the king's troops. Soon afterwards he was attacked, and killed in the heat of action. Nor was the envy of his enemies even then satiated. His body was denied burial, and at length taken away privately by the peasants. But his virtue, however hated in courts, was adored by the uncorrupt part of his countrymen. At length, by an inspection of his papers, the king saw, when it was too late, the injustice which had been done to the man who had behaved so well in a high and difficult office; and his papers discovered indications of further benefit contemplated for the king and his dominions. In consequence of these discoveries, the duke's adherents were declared loyal subjects, all prosecutions were ordered to cease, and the king desired the body of Coimbra to be transported with great pomp from the castle of Abrantes to the monastery of Batalha, where it was interred in the tomb which he had caused to be erected there for himself.

PEEBLESSHIRE, or TWEEDDALE, a county in Scotland, situated between 55. 24. and 55. 50. north latitude, and between 2. 45. and 3. 23. west longitude from Greenwich. It is bounded on the north by Mid-Lothian or Edinburghshire, on the east by the county of Selkirk, on the south by Dumfriesshire, and on the west by Lanarkshire. Its greatest extent from north to south is about thirty miles, and its greatest breadth from east to west about twenty-two; the contents being 229,778 English acres, of which only about a tenth part is fit for cultivation. It is divided into sixteen parishes, twelve of which form the presbytery of Peebles, and four belong to that of Biggar, but all are under the synod of Lothian and Tweeddale.

The surface of this county is hilly, and towards the south mountainous, several of the high grounds in that quarter, such as Hartfield, Harstane, Broadlaw, and Dollarlaw, being from 2800 to nearly 3000 feet above the level of the sea. The general elevation of the pasture lands is about 1200 feet; yet, with few exceptions, the hills are covered with green herbage, heath being almost confined to a few of the highest ridges on the south-east. On the banks of its streams are many pleasant and fertile spots; but, from the want of wood, the general appearance is naked and uninteresting; though of late great attention has been paid to planting, and it is estimated that there are now nearly 7000 acres under wood. The soil of the cultivated land, lying chiefly on the sides of the lower hills and the banks of the streams, is for the most part a light loam, with clay, moss, and moor on the high grounds. Coal, limestone, and freestone abound in the parishes of Linton and Newlands, on the north side of the county, and in the latter ironstone is also found. Limestone and freestone are worked profitably in the parish of Linton; but the coal formerly obtained from Newlands has been abandoned, as not repaying the cost of outlay. Lime, however, may still be purchased at Magbiehill, the coal for burning which is brought from Linton. At Stobo, slate of a good quality is quarried, and sold with advantage to the proprietor. In the parish of Traquair there is also a slate quarry in active operation. The river Tweed, from which this district is often called Tweeddale, rises from a well of the same name, in the parish of Tweedsmuir, in the south-western extremity of the county, about 1500 feet above the level of the sea, and, flowing first north-east and then east, dividing the county into two nearly equal parts, it passes into Selkirkshire at Gatehaup Burn, after a winding course of about thirty-six miles. The Annan and the Clyde have their source in the same hill. Of the other streams, here called *waters*, the most considerable are Biggar, Lyne, Peebles or Eddlestone, Leithan, Mannor, and Quair, which fall into the Tweed; and the North and South Esks, which pursue their course into Mid-Lothian. The lakes or lochs are St Mary's, Waterloch, and Slipperfield. These, as well as the rivulets, abound in the common fresh-water fish, and most of the streams are occasionally frequented by salmon; but salmon are not found in such numbers, even in the Tweed, within the bounds of this county, as to afford a fishery that will pay rent.

The climate of Peeblesshire, owing to its elevation and want of shelter, is perhaps more rigorous than that of any other of the southern counties of Scotland. Cold easterly winds prevail in spring, and greatly retard vegetation; whilst in summer frosts often occur, which injure the potato and other crops; and the winters are frequently so severe as to destroy turnips, the snow lying so deep and so long as sometimes to occasion great loss amongst the flocks.

As this is almost exclusively a pastoral country, the farms are in general large, most of them being from 1000 to 4000 acres. On the arable land they are small, the greater number being below 100 acres. These are in general held on leases for nineteen years, as in other parts of Scotland. Taking the extent and rental as before stated, the average would be nearly five shillings the English acre. This is chiefly derived from live stock, especially sheep, of which there may be about 120,000. These were formerly of the black-faced heath variety, sometimes called Tweeddale sheep, from the name of the county, or Linton sheep, from the name of a village on the northern side of the district, where great fairs are held for the sale of them; but of late years the Cheviot breed, which bears a much more valuable fleece, has been established on many of the lower hills, and the majority of those now fed in the county are of this variety. The crops are the same as in other parts of Scotland, excepting that wheat is cultivated only upon a very small scale. A variety of oats called the *red oat*, and sometimes the *Mag-*

biehill oat, from its being first cultivated here on that estate, is very well adapted to high and exposed situations, both because it ripens earlier than the common kind, and is less liable to be beaten out by wind, whilst on good land it is found to be highly productive.

Many of the proprietors have seats distinguished either for their antiquity or their beauty; but the Earl of Traquair is the only nobleman who now resides in the county. Peeblesshire, in 1811, was divided into about eighty estates, many of them large, but not valuable in proportion. The valuation of the whole is L.51,937. 13s. 10d. Scotch; and the real rent, as assessed for the property-tax that year, was, for the lands L.57,382 sterling, and for the houses L.2568. Two thirds of the estates are valued under L.500 Scotch, a sum which may indicate pretty nearly their present yearly value in sterling money; and little less than two thirds of the whole are entailed.

In the county there are several remains of Roman camps. Drochil Castle in the parish of Newlands, and Nedpath Castle in the parish of Peebles, are the only two which are in tolerable preservation; but vestiges of ancient castles or towers abound in the whole valley of the Tweed. The remains of the Castle of Tinnes or Thanes are six feet in thickness, and the mortar is as hard as the stone.

The inhabitants are generally educated, intelligent, and attentive to religious duties, though few of the labouring classes or shepherds consider poaching as in any degree criminal, and accordingly practise it to a considerable extent, both by land and water. To this they are tempted by the abundance of the game, which in some districts is most destructive to the poor. The principal towns or villages in Peeblesshire are, Peebles, Linton, Eddlestone, Skirling, Broughton, and Innerleithen. At this latter place, Lord Traquair, the proprietor of the village, has erected a neat building with corridor over a mineral well, which for some years past has attracted numerous visitors to the village during the summer.

The royal burgh of Peebles formerly joined with Selkirk, Lanark, and Linlithgow, in returning a member for the burghs; but since the passing of the reform act, the burgh is merged in the county, and both united return a member to serve in parliament; the qualification to vote for a candidate being the same in the burgh as in the county, viz. ten pounds property, or fifty pounds rental per annum. At the passing of the reform act there were, of old constituency forty-seven, new constituency 300; but, in consequence of the creation of votes for party purposes, there are now 760 electors on the poll-books.

PEEBLES, the county-town, is not distinguished for any particular trade or manufacture. The majority of the operatives are hand-loom weavers, whose wages do not average more than from five to seven shillings per week; the remainder of their living being procured by fishing, harvest-work, &c. It is not known when Peebles was erected into a royal burgh; but in 1357 the burgh sent two members to parliament. The property of the burgh, consisting of lands, mills, &c. yields an annual revenue of L.1343. 11s. 2d., which is expended in salaries to teachers, in paving and lighting the streets, supplying the town with water, and other useful purposes. The whole matters of police are regulated by a provost, two bailies, a treasurer, dean of guild, and twelve councillors, chosen by the inhabitants. Considerably more property was secured to the burgesses and inhabitants by charter of James VI. dated the 10th of November 1621; but, as in most of the other burghs, this was dissipated by the members of the corporation. Peebles is divided into the old and the new town; and it is bounded on the south by the Tweed, and on the north by the Eddlestone Water. It is worthy of remark, that the Tweed runs almost from due west to east, whilst the Eddlestone Water, on the other side of the town, flows exactly in the contrary direction. The population returns for the burgh and parish were, in 1811, 2485; in 1821, 2701; and in 1831, 2750. The real value is estimated at L.9255. Peebles is distant twenty-two miles south of Edinburgh.

PEEK, in nautical language, is a word used in various senses. Thus the anchor is said to be a-peek when the ship, being about to weigh, comes over her anchor in such a manner that the cable hangs perpendicularly between the hawse and the anchor.

To heave a-peek is to bring the peek so that the anchor may hang a-peek. A ship is said to ride a-peek when, lying with her main and fore-yards hoisted up, one end of her yards is brought down to the shrouds, and the other raised up on end; which is chiefly done when she lies in rivers, lest other ships, falling foul of the yards, should break them. Riding a broad peek denotes much the same thing, excepting that the yards are only raised to half the height.

Peek is also used for a room in the hold, extending from the bitts forward to the stern. In this room men of war keep their powder, and merchantmen their provisions.

PEEL, a town on the western side of the Isle of Man, in the Irish Channel, formerly called Holm. It is a scattered place, containing nothing remarkable excepting an old cathedral in a dilapidated state, and a castle on a small island, or rather rock, at the mouth of the river of the same name as the town. It has but little trade, and about 1300 inhabitants.

PEELAS Isles, a cluster of small islands in the Eastern Seas. Plenty of cowries are found along the beach. The Peelas are covered with wood, but are destitute of fresh water, and have no settled population.

PEER, in general, signifies an equal, or one of the same rank and station. Hence, in the acts of some councils, we find these words: " with the consent of our peers, bishops, abbots," and others. Afterwards the same term was applied to the vassals or tenants of the same lord, who were called peers, because they were all equal in condition, and obliged to serve and attend him in his courts; and peers *in fiefs*, because they all held fiefs of the same lord.

Peer *of the Realm*, a lord who has a seat and vote in the House of Lords, which is also called the House of Peers. These lords are called peers, because, though there is a distinction of degrees in our nobility, yet in public actions they are equal; as in their votes in parliament, and in trying any nobleman or other person impeached by the Commons. See Parliament.

PEERESS, a woman who is noble by descent, by creation, or by marriage. As we have noblemen of several ranks, so we may also have noblewomen. Thus Henry VIII. made Anne Boleyn, Marchioness of Pembroke; James I. created the Lady Compton, wife of Sir Thomas Compton, Countess of Buckingham, in the lifetime of her husband, without any addition of honour to him; the same king also made the Lady Finch Viscountess of Maidstone, and afterwards Countess of Winchilsea, to her and the heirs of her body; and George I. made Lady Schulenberg Duchess of Kendal. If a peeress, by descent or creation, marry a person under the degree of nobility, she still continues noble; but if she obtain that dignity only by marriage, she loses it on her afterwards marrying a commoner; yet, by the courtesy of England, she generally retains the title of her nobility.

PEERGAUM, a town of Hindustan, in the Mahratta territories, and in the province of Aurungabad, sixty-eight miles east from Poonah. Long. 75. 2. E. Lat. 18. 32. N.

PEGASUS, amongst the poets, a horse imagined to have had wings, being that on which Bellerophon was fabled to have mounted when he engaged the Chimæra.

Pegasus, in *Astronomy*, the name of a constellation of the northern hemisphere, in the form of a flying horse.

PEGAU, a city of the kingdom of Saxony, situated in the circle of Leipsich, and bailiwick of Borna. It is built on the banks of the White Elster, and contains two churches, 420 houses, and 2680 inhabitants, employed in making various kinds of linen goods, and also as shoemakers.

PEGMARES, a name by which certain gladiators were distinguished, who fought upon moveable scaffolds called *pegmata*, which were sometimes unexpectedly raised, and by this means surprised the people with gladiators in hot contention. These scaffolds were sometimes lifted up so suddenly as to throw the combatants into the air; and sometimes they were let down into dark and deep holes, and then set on fire, thus becoming the funeral piles of those miserable wretches, and roasting them alive to divert the brutal populace.

PEGU, formerly an independent kingdom of Asia, now incorporated with the Birman empire, by whose sovereign it was subdued, after long wars. The limits of this state were never very accurately defined, and it probably varied with the fate of war. It included a large tract of country, about 350 miles in length from north to south, and as much in breadth from east to west, situated on and comprising a large portion of the delta of the Irrawaddy. Arracan and Ava were its northern boundaries, Siam its limit on the east, on the south Siam and the sea, and on the west the Bay of Bengal and part of Arracan.

This country, being intersected by the Irrawaddy and its branches, is fertile and well watered; but, owing to the desolations of war, it is wild and uncultivated, overrun in many places with jungle or rank luxuriant grass, affording cover for wild animals, such as tigers, elephants, buffaloes, deer, and other animals. Both banks of the river are covered everywhere with a narrow belt of tall reedy grass. The country from Rangoon throughout is a low champaign. As far as the tide reaches it is covered with a narrow belt of tall reedy grass, and behind with a thick and continuous forest of moderate-sized trees, amongst which the most frequent and remarkable are the *sonneratia appetalu*, and *heritiera fomes*. Here and there are a few grassy plains. The character of the vegetation changes where the influence of the tide ceases. The country is then covered with a tall rushy grass, a species of saccharim, amongst which are scattered trees of from twenty to sixty feet in height. There is very little appearance of inhabitants along the shores of the river, which ought to be the most populous portion of the country. Here and there, on the immediate banks, are a few fishing villages, and in the interior other agricultural villages, with a few patches of rice culture about them. The only culture of any extent is that of the banana, of which extensive groves line the sides of the river. In some parts advantage is taken of the vicinity of the river for the purposes of irrigation; but in general the country is nearly in a desolate state. Symes, who was sent as ambassador to Ava, gives a similar description of the country. " The country round," he observes, " as far as our view could reach, displayed a level plain, with clumps of trees at distant intervals; a thick reedy grass had grown in some places very high; in others, where it had been burnt, there appeared good pasturage for cattle; we saw the embanked divisions of a few rice plantations, and discovered the vestiges of former culture and population; but during a walk of two hours the eye was not gratified with the sight of house or inhabitant. Desolated by the contentions of the Birmans and Peguans, the country had not yet recovered from the ravages of war. In our walk we observed many tracks of wild elephants, the spots where hogs had rooted and deer lain, and found the remains of two antelopes that had recently been killed, and were half devoured by tigers. The walks on each side of the river are low, and the land seems adapted to produce excellent crops; but it is now quite deserted, and become the undisputed domains of the wild beasts of the forest." The chief produce of the country is rice; but where those who sow are not sure that they shall reap the fruits, they seldom cultivate more than suffices for their immediate subsistence; and to such grievous oppression have the people often been subjected, that they have been forced to abandon their villages and fly into the woods, where they have cultivated small patches of ground, and lived principally upon fish, fowl, venison, and reptiles. The country around Pegu, the capital, was completely laid waste by the victorious troops of Alompra, when he conquered that city in 1757; and to such oppressions were the Peguans subjected, that the country, though fruitful in the extreme, and one of the fairest and most healthful on the globe, has never recovered its former prosperity. The subjugation of the people by the Birmans ushered in a long era of tyranny and persecution, under which, though mitigated, they still suffer. Severe penal laws were imposed on the Taliens or native Peguans. But these have been abrogated by the present sovereign; justice has also been more impartially administered; and it is mentioned by Symes, that the only distinction between the subjected Peguans and the Burmese is the exclusion of the former from all places of public trust and power. The people have also been more reconciled to the Birman yoke by other proceedings of the present monarch, especially by the order which he issued for rebuilding Pegu the capital, encouraging settlers by grants of ground, and inviting the scattered families of former inhabitants to return and re-people their deserted city. The preservation and embellishment of the ancient national temple of Shoomandoo, which has been ordered by the government, is also a popular act. These measures do not appear, however, to have conciliated the Peguans, as Mr Crawford, who visited the country, mentions that in 1827 they had risen in rebellion against the authority of the Burmese; and he was himself a witness to an action between the two contending parties.

Pegu possesses mines of iron, tin, and lead; also of precious metals, namely, rubies, sapphires, and rock crystal. Its most valuable produce, however, is the teak timber, used for ship-building, which is impervious to worms or the bad effects of salt water. The trees, some of which are sixty feet in length by nine in girth, are floated down the Irrawaddy and its tributaries during the rainy seasons. This river is the largest in the country, and, about a hundred miles from the sea, divides into numerous branches, the principal being those of Persaim and Rangoon, which overflow an extensive tract during the rainy season. The Sitang, another large river, flows into the Gulf of Martaban. The principal ports are Siriam, Negrais, and Rangoon.

The history of the eastern nations is for the most part involved in darkness, until the period when the Europeans, in the progress of navigation, found out a maritime route to India; and we learn from the testimony of the Portuguese historians, that about this time four powerful states divided amongst them the regions which lie between the south-east province of British India, Yunan in China, and the Eastern Sea. These states were distinguished amongst the Europeans by the names of Arracan, Ava, Pegu, and Siam; and, from all that is known respecting them, it appears that they carried on constant wars with each other, and with various success. It is mentioned on the authority of Mendez Pinto, that the Birmans, though formerly subject to the king of Pegu, became afterwards masters of Ava, and caused a revolution in Pegu about the middle of the sixteenth century. Their supremacy continued throughout the seventeenth and also during the first forty years of the last century, when the Peguans in the provinces of Dalla, Martaban, Tongo, and Prome revolted, and a civil war ensued, which was carried on by both parties with the most revolting ferocity. In the year 1744 the British factory at Siriam was destroyed by the rage of the contending parties. After a tedious and protracted war, which was long doubtful, the Peguans, aided with arms by European traders, and joined by renegade Dutch and Portuguese adventurers, gained important advantages over the Birmans, in the years 1750 and 1751. They finally invested Ava, the capital, which the Birmans, disheartened by defeat, surrendered at discretion, and Dweepdee, the last of a long line of kings, was made prisoner with all his family, excepting two sons, who fled to the Siamese, from whom they met with a friendly reception, and with assurances of succour. Apporaza, the brother of the king of Pegu, was left in Ava, the capital, to complete the reduction of the Burmese. But a deliverer unexpectedly arose to the Birmans, in the person of the celebrated Alompra, who was of low extraction, but endowed with a spirit of boldness and enterprise which qualified him for great achievements. He had collected around him a hundred devoted followers, on whom he could rely; and, availing himself of the favourable opportunity when the Birmans were exasperated by oppression, and when the garrison of Ava had been greatly diminished, he attacked the Peguans with irresistible fury, and put every man to the sword. He then retreated to the fort of Monchaboo, where he repelled the feeble assaults of the Peguans, and became the assailant in his turn, attacking and defeating their scattered forces, and finally advancing, by a bold and well-concerted movement, to Ava, of which he took possession. A large armament was now fitted out by the king of Pegu, the command of which was given to Apporaza, who, ascending the stream of the Irrawaddy, appeared before Ava, which he summoned to surrender, but which Shemhuan, the lieutenant of Alompra, declared that he would defend to the last extremity. Alompra had in the mean time collected a formidable fleet, which Apporaza proceeded to attack. The action, which was obstinate and bloody, terminated in the entire discomfiture of the Peguan general, who retired with the wreck of his army to his own country. This action took place in 1754. An alarm was at this time spread in Pegu, that the Birmans in that city were engaged in a conspiracy against the government, upon which the terrified inhabitants flew to arms, and having murdered the deposed monarch, who was detained in prison, they proceeded to put to death every Birman who was found within the city. This act of cruelty was the signal for a general revolt of the Birmans throughout the empire, who retaliated the barbarity of their oppressors, and quickly made themselves masters of Prome, Denobew, Loonzay, and other places. The monarch of Pegu, Beinga Della, alarmed by this disastrous intelligence, levied a new army, with which he marched from Pegu, and commenced the siege of Prome. The city made a resolute defence; and the besiegers, repelled in several attacks, were forced to convert the siege into a blockade. Alompra detached part of his fleet and army to the aid of the besieged, and forty days afterwards followed with his choicest troops. He immediately commenced an attack on the works of the besiegers, who, defeated in a long, close, and bloody action, were at length compelled to seek safety in a precipitate flight. Alompra did not fail to improve his victory. He commenced an active pursuit, and his troops advanced within a few leagues of Bassein unmolested by the enemy. The intelligence of this disaster spread consternation throughout the dominions of Pegu; the king retired from Bassein to his capital; his adherents, abandoned and terrified, consulted each his own safety, and the town and fort of Persaim were completely deserted. Each party was at this time anxious to procure the aid of the French or English, who had factories at Syriam, and who alternately espoused the one or the other side, according as it seemed to suit their interests. Many skirmishes ensued, and the war was for some time carried on without any decisive success on either side. The Birmans, however, supported by the vigour and capacity of Alompra, were making slow but sure advances, and in April 1755 that chief gained a decided victory over Apporaza, in his camp at Synangong. The Peguans, disheartened, fled to Syriam, and many did not halt till they reached Pegu itself. The Birmans soon afterwards took possession of Rangoon; and an attempt to recover the place by the Peguans was repulsed with loss. It was again attacked by the Peguans, aided by three English ships, and the Birmans were driven from their boats. They still, however, maintained their position on shore till their enemies retreated. In July 1756, Syriam was taken by assault, and its fall may be said to have decided the contest. As soon as the rainy season subsided, and the low and swampy country which lies between Pegu and Syriam had emerged from the inundations of the monsoon, Alompra ordered his general to advance towards Pegu with a strong body of troops. The whole army followed a few days afterwards, and in four days reached the city, marching through a wasted country. The city of Pegu was occupied by the royal family, and the principal nobles of the nation. Alompra, according to the usual tactics of the Birmans, had recourse for the reduction of the city to blockade, rather than to the doubtful attempt of an assault. The Peguans, reduced to the utmost straits, were forced at last to surrender the city, which was given up to indiscriminate plunder; a decisive blow was thus given to the independence of Pegu; and Alompra, improving his victory, proceeded to bring into subjection the countries to the eastward, including the fertile districts between Pegu and the three pagodas, which were the ancient boundaries of Pegu and Siam. From this period the kingdom of Pegu has been incorporated with the Burmese dominions; and the Peguans, though occasionally rebelling, have never been able to shake off their oppressive yoke.

Pegu, the capital of the former kingdom of Pegu, situated on the Sitang, formerly a large and populous city, the extent of which may be still traced in the ruins of the walls. These were composed of brick badly cemented with clay, about thirty-five feet thick, with small equidistant bastions about 300 yards asunder. The ditch was about sixty yards in breadth, and ten or twelve feet in depth. The ancient city was razed to the ground by the conqueror Alompra, when he took it in 1757, with the exception of the temples, which are numerous; and of these, the great temple of Shoomandoo has alone been renewed and kept in repair. Europeans who visited this city in the year 1600, describe it as a place of great splendour, the streets spacious, and running in a straight line from gate to gate. The king's palace, with walls and ditches, stood in the middle of the town, built like a fortress; but the interior apartments were all composed of wood with gilt roofs, and the population amounted to 150,000.

As stated in the former article, orders were issued by the Birman monarch to rebuild the ruined city; and the governor of the province was induced to quit Rangoon and to make Pegu his future residence. These measures so far succeeded that a new town was built on the site of the ancient city; and the inhabitants, consisting chiefly of the priests, the followers of the court, and a few poor families, now amount to 7000. The great proportion of the former inhabitants are either extinct, or have been dispersed over the whole extent of the empire. The new city of Pegu is built on the plan of the former city, and occupies about one half of its area; it is fenced round by a stockade from ten to twelve feet high. The plan of the new town is that of one main street running east and west, crossed at right angles by two smaller streets not yet finished. At each extremity of the principal street there is a gate in the stockade, which is defended by a wretched piece of ordnance and a few musqueteers. There are two inferior gates on the north and south sides of the stockade. The streets are spacious, like those of most Birman towns; and the town is paved with brick, large supplies of which are found in the old ruins. All the houses, even those of the meanest classes, are raised from the ground, either on wooden posts or bamboos, according to the size of the building. The monasteries of the priests, and the habitations of the higher classes, are raised to the height of six or eight feet. The houses are all made of mats or sheathing boards, the use of brick or stone in private buildings being prohibited by a royal edict. The dwellings being composed of such combustible materials, the inhabitants are in continual dread of fire; and almost every house has earthen pots filled with water on the roof; and a class of firemen perambulate the streets day and night. The roofs are lightly covered; and, as an additional precaution against fire, at each door stands a long bamboo, with an iron hook at the end, to pull down the thatch. There is also another pole with a grating of iron, to suppress flame by pressure. The house of the maywoon or viceroy is a spacious building, possessing, however, few ornaments; gilding is forbidden to all subjects in the Birman empire; few have even the liberty to paint the pillars of their house, or to use lacker; and the naked wood gives an unfinished appearance to their houses, however roomy or well adapted to their purposes. The great object that attracts attention in Pegu is the noble edifice of Shoomandoo or the Golden Supreme. This extraordinary pile of building is erected on double terraces, one raised upon another; the lower and greater terrace, about ten feet above the natural level of the ground, forming an exact parallelogram; the upper and lesser terrace is similar in shape, and rises about twenty feet above the lower terrace, or thirty feet above the level of the ground. These terraces are ascended by flights of stone steps. The temple is pyramidal, composed of brick and mortar, without excavation or aperture of any sort; it is octagonal at the base and spiral at the top, and each side measures at the base 162 feet. This breadth diminishes abruptly, so that its form has been compared to that of a speaking trumpet. The extreme height of the edifice from the level of the country is 361 feet; and on the top is an iron tee or gilded umbrella, seen on every building in the Birman dominions, fifty-six feet in circumference. All around the steps or ascent are placed innumerable marble images of Gaudama their saint. The Rahaans or attendant priests assert that the foundation of this temple was laid two thousand years ago, and that it was brought to its present state of magnificence by successive monarchs. On the south-east angle of the upper terrace are two handsome saloons, supported on pillars sixty feet in length by thirty in breadth; at each angle of the interior and higher terrace is a temple sixty-seven feet in height, resembling in miniature the great temple; and in front are four gigantic representations in masonry of Palloo the evil genius, half beast, half man, seated on his hams, with a large club on the right shoulder. Long. 96. 12. E. Lat. 17. 10. N.

PEIHO, a considerable river of China, in the province of Pe-che-lee. It has its rise on the borders of Tartary, and in its course northwards passes within a few miles of the capital, maintaining its communication, by the great canal, with the Yellow Sea, into which it discharges itself in lat. 39. 3. N. The country through which it flows is mostly a dead flat, and the tide is perceptible 400 miles from its mouth.

PEINA, a city of the kingdom of Hanover, in the province of Hildesheim, the capital of a bailiwick of the same name, situated on the river Fuse. It is surrounded with walls, and contains a castle used now as a workhouse, a Catholic and a Lutheran church, a capuchin monastery, 440 houses, and 3460 inhabitants, employed chiefly in spinning and weaving linen goods, and in agriculture. Long. 10. 6. 31. E. Lat. 52. 19. 34. N.

PEINE Forte et Dure (Lat. *pœna fortis et dura*) signifies a special punishment inflicted on those who, being arraigned of felony, refuse to put themselves on the ordinary trial, but stubbornly stand mute. It is vulgarly called *pressing to death.*

PEINGHEE, a town in the Birman empire, on the western side of the Irrawaddy. The teak timber grows in the western mountains, which are in sight, in great abundance, and is carried to Rangoon, whence it is exported to the British territories. Here also ships are built, although the distance from the Rangoon, including the windings of the river, is 150 miles. Long. 94. 50. E. Lat. 18. 31. N.

PEIRCE, James, an eminent dissenting minister, born at Wapping, London, in the year 1674. He was educated at Utrecht and Leyden; after which he spent some time at Oxford, in order to enjoy the benefit of frequenting the Bodleian Library. He then for two years preached the Sunday-evening lecture at the meeting-house in Miles Lane, London, and afterwards settled at Cambridge. In 1713 he was removed to a congregation at Exeter, where he continued until the year 1718; when the Calvinists amongst the dissenters having proposed a subscription to articles of faith, which were to be signed by all the dissenting ministers in the kingdom, he refused, and was consequently ejected from his congregation. Upon this, a new meeting was opened at Exeter, of which Mr Peirce continued minister till his death in 1726. He was a man of strict virtue, exemplary piety, and great learning; and he wrote, 1. Exercitatio Philosophica de Homœmeria Anaxagorea; 2. Thirteen pieces on the Controversy between the Church of England and the Dissenters; 3. Ten pieces on the Controversy about the Ejectment at Exeter; 4. Six pieces on the Doctrine of the Trinity; 5. A Paraphrase and Notes on the Epistles of St Paul to the Colossians, Philippians, and Hebrews; 6. An Essay in favour of giving the Eucharist to Children; and, 7. Fourteen Sermons.

PEIRESC, Nicolas Claude Fabri, born in 1580, was descended from an ancient and noble family, which had been originally established at Pisa in Italy. At ten years of age he was sent to Avignon, where he spent five years in the Jesuits' college, studying what in Scotland and on the Continent is called *humanity.* From Avignon he was, in 1595, removed to Aix, and entered upon the study of philosophy. In the interim, he attended the proper masters for dancing, riding, and handling arms, in all which, though he performed the lessons regularly, it was with reluctance; for this being done only to please an uncle, whose heir he was to be, he never practised by himself, esteeming all the time lost which was not spent in the pursuits of literature. During this period, his father being presented with a medal of the Emperor Arcadius, which had been found at Belgenser, Peiresc begged the favour of it; and, charmed with deciphering the characters in the exergue, and reading the emperor's name, he carried the medal, in a transport of joy, to his uncle, who for his encouragement gave him two more, together with some books upon the subject. This is the epoch of his application to antiquities, for which he became afterwards so famous. In 1596, he was sent to finish his course of philosophy under the Jesuits at Tournon, where he turned his attention particularly to cosmography, as being necessary to the understanding of history; abating, however, nothing of his application to antiquity, in which he was assisted by Petrus Rogerus, one of the professors, and a skilful medallist. Nor did he neglect the study of humanity in general, in which he was the master and instructor of a brother who lived with him. But to do all this he was obliged to sit up late at night; and as he was naturally of a feeble constitution, so much labour and attention increased the weakness of his stomach, formerly contracted, and for which he had used a kind of digestive powder. Being recalled by his uncle in 1597, he returned to Aix, and there entered upon the study of the law, which he prosecuted, however, so as to find leisure to visit and converse frequently with Bagarr, a most skilful antiquary, who was afterwards master of the jewels to Henry IV.

The following year he went again to Avignon, to carry on his course of law under one David, who being also well skilled in antiquities, was pleased to see Peiresc join this study to that of the law. But Ghibertus of Naples, auditor to Cardinal Aquaviva, fed his curiosity the most, in showing him some rarities, such as he had never seen before. Having now spent almost three years in Italy, he began to prepare for his departure, and in the end of 1602, having packed up all the rarities, gems, and other articles which he had procured, and despatched them to Marseilles, he left Padua, and, crossing the Alps of Geneva, proceeded to Lyons. From Lyons he went to Montpellier, to improve himself in law under Julius Parius. From Montpellier he despatched more rarities to his uncle, and arrived at Aix in November; but having brought Parius along with him, he obtained leave to return in a few days to Montpellier. He accompanied Parius back again, and under him continued pursuing his legal studies till the end of 1603, when he returned to Aix, at the earnest request of his uncle, who, having resigned to him his senatorial dignity, had ever since the beginning of the year laboured to get the king's patent. The degree of doctor of laws was a necessary qualification for this dignity. Peiresc, therefore, having performed the usual exercise, took that degree, in January 1604, when the patent was given to the senate, and ordered to be recorded; yet Peiresc procured leave not to be presently entered into the list of senators. The bent of his inclination was not so much to business as to advancing arts and sciences, and assisting all the promoters of learning. For this purpose, he resolved to lead a single life; so that when his father had concluded a match for him with a respectable lady, he begged to be excused.

In the year 1605 he accompanied Varius, first president of the senate at Aix, who was very fond of him, to Paris, whence, having visited every thing curious, he, in 1606, crossed the Channel to England, in company with the king's ambassador. He was very graciously received by King James I.; and having seen Oxford, and visited Camden, Sir Robert Cotton, Sir Henry Saville, and other learned men, he passed over to Holland. After visiting the several towns and universities, with the literati in each, he passed through Antwerp to Brussels, and thence returned to Paris to witness the ceremony of the Dauphin's baptism, which was solemnized on the 24th of August 1606.

In 1629 he began to be much tormented with strangury and hæmorrhoids; and in 1631, having completed the marriage of his nephew Claudius with Margaret Alresia, a noblewoman of the county of Avignon, he bestowed upon him the barony of Rians, together with a grant of his senatorial dignity, only reserving the function to himself for three years. But the parliament not waiting for his surrender of it, he resented that affront so heinously, that in 1632 he procured letters patent from the king to be restored to the exercise of his office during five years longer, which happened to be till the time of his death; for, being seized, in June 1637, with a fever, which brought on a stoppage of urine, this put an end to his life, in the fifty-seventh year of his age.

The works which he published are, 1. Historia provinciæ Galliæ Narbonensis; 2. Nobilium ejusdem provinciæ Familiarum Origines, et separatim Fabriciæ; 3. Commentarii rerum omnium memoria dignarum sua ætate gestarum; 4. Liber de ludicris Naturæ operibus; 5. Mathematica et astronomica varia; 6. Observationes mathematicæ; 7. Epistolæ ad S. P. Urbanum VIII. Cardinales Barberinos, &c.; 8. Authores antiqui Græci et Latini de ponderibus et mensuris; 9. Elogia et Epitaphia; 10. Inscriptiones antiquæ et novæ; 11. Genealogia domus Austriacæ; 12. Catalogus librorum Bibliothecæ regiæ; 13. Poemata varia; 14. Nummi Gallici, Saxonici, Britannici, &c.; 15. Linguæ orientales, Hebræa, Samaritana, Arabica, Egyptiaca, et Indices librorum harum linguarum; 16. Observationes in varios auctores.

PEKIANGHO, a considerable river of China, in the province of Quangtong, having its origin on the southern side of the mountains by which that province is divided from Kiangsee. It forms part of the great navigable communication between Peking and Canton.

PEKING, or Pekin, a celebrated city of Asia, and capital of the great empire of China. It is built in the form of an oblong square, of which the four walls face the cardinal points, and enclose an area of about fourteen square miles, independently of the suburbs, which are very extensive. The walls are built of brick, and are thirty feet in height. In the south wall there are three gates, and in each of the other sides two, from which it is sometimes called the city with nine gates; but its usual name is *Peking*, or the Northern Court. The city is divided into two parts; namely, the old city, which is inhabited by the Chinese; and the new city or the imperial city, which is inhabited by the Tartars. It is in the shape of a parallelogram, and is about a mile in length from north to south, and three fourths of a mile from east to west. The middle gate on the south side opens into this space; and it is surrounded by a wall built of large red polished bricks, twenty feet in height, covered with a roof of tiles painted yellow and varnished. Here are contained the imperial palace and gardens, all the tribunals or public offices of government, and lodgings for the ministers, eunuchs, artificers, and tradesmen belonging to the court. Within the enclosure flows a winding rivulet, which being formed into canals, basins, and lakes, with artificial mounts, rocks, and groves, exhibits a lively imitation of the picturesque and the beautiful in natural scenery. The imperial palace of Yuen-mien, which is situated without the city, is even on a larger scale, the grounds being at least ten miles in diameter, and comprising an area of 60,000 English acres, laid out, like the grounds in the palace within the walls, in representing all the great features of nature, namely, lakes, mountains, forests, rocks, and rivers, which are thrown together with an irregular boldness of style that has a striking effect. These grounds contain thirty distinct places of residence for the emperor, besides a village of considerable size. These buildings, however, are remarkable for their meanness, resembling rather cottages than palaces. Even the very dwelling of the emperor, and the grand hall of audience, when divested of their colour and gilding, are not much superior to the barns of an English farmer. Nor is any rule of proportion studied in the construction of these apartments. The length of the audience-hall is a hundred and ten feet, by forty-two in breadth, and the height is twenty feet. The ceiling is embellished with circles, squares, and polygons, and loaded with a great variety and glare of colours. The throne, placed in the recess, is adorned with exquisite carving. It is supported by rows of pillars painted red, and consists entirely of a wood resembling mahogany. Between the other two gates in the south and north walls run two streets in a straight line, four English miles in length, and about a hundred and twenty feet in breadth. These are crossed by one street of the same breadth, which runs from the gate of the eastern wall to the opposite gate on the west. There is another street which runs in the same direction; but it is interrupted in its progress by the north wall of the imperial city, round which it is carried. The cross streets, which branch off from the main streets at right angles, are merely lanes, being very narrow. They are all unpaved, and covered with sand and dust, but are frequently watered, and kept very clean. The houses are low, few being more than one story in height; not a chimney is to be seen rising above the ordinary level; and this circumstance, together with the regularity of the streets, all laid out in straight lines, give to the city the appearance of an encampment. None but the great shops have either windows or openings in the front wall, though most of them have a sort of terrace, with a railed balcony or parapet wall in front, ornamented with flowers, shrubs, or stunted trees. The principal streets have on each side a line of buildings, consisting entirely of shops and warehouses, in front of which the goods are displayed; and large wooden pillars are erected higher than the houses, on which are notified in gilt characters the nature of the goods to be sold, and the honest character of the dealers, and which are, besides, decorated with various-coloured flags, and streamers and ribands from top to bottom, exhibiting the appearance of a line of shipping dressed in the colours of all the different nations of Europe. Nor are the sides of the houses less brilliant in the several colours in which they are painted, consisting generally of sky-blue or green, mixed with gold; and amongst the articles which make the most splendid show are the coffins for the dead, and the funeral biers, which vie in their expensive trappings with the marriage cars. Barrow, who visited China with Lord Macartney's embassy, gives a lively description of the animated scene which the first *coup d'œil* of the streets presented to the view. "The multitude of moveable workshops," says Mr Barrow, "of tinkers and barbers, cobblers and blacksmiths; the tents and booths where tea and fruit, rice and other eatables, were exposed for sale, with the wares and merchandise arrayed before the doors, had contracted the spacious street to a narrow road in the middle, just wide enough for two of our little vehicles to pass each other. The cavalcade of officers and soldiers that preceded the embassy; the processions of men in office, attended by their numerous retinues, bearing umbrellas, and flags, and painted lanterns, and a variety of strange insignia of their rank and station; different trains that were accompanying with lamentable cries corpses to their graves, and, with squalling music, brides to their husbands; the troops of dromedaries laden with coals from Tartary, the wheelbarrows and hand-carts stuffed with vegetables; occupied nearly the whole of this middle space in one continued line, leaving very little room for the cavalcade of the embassy to pass. All was in motion. The sides of the streets were filled with an immense concourse of people buying and selling, and bartering their different commodities. The buzz and confused noises of this mixed multitude, proceeding from the loud bawling of those who were crying their wares, the wrangling of others, with every now and then a strange twanging noise like the jarring of a cracked Jew's harp, the barber's signal made by his tweezers, the mirth and laughter that prevailed in every group, could scarcely be exceeded by the brokers in the bank rotunda, or the Jews and old women in Rosemary Lane. Pedlars with their packs, and jugglers and conjurers, fortune-tellers, mountebanks, quack-doctors, comedians and musicians, left no space unoccupied." Tartar women are commonly seen amongst the crowd, either walking or riding on horses, which they bestride like men. The Chinese women are, however, rigidly confined to the house in Peking, as in other parts of the empire.

Of the ornamental structures to be seen in Peking, the most remarkable are three singular erections at the four points where the great streets intersect each other, called triumphal arches, but which are rather monuments to the memory of distinguished characters, especially of those who have attained to extraordinary longevity. They are formed sometimes of stone, but generally of wood; and consist of a large central gateway, with a smaller one on each side, all covered with narrow roofs; and, like the dwelling-houses, they are splendidly painted, varnished, and gilt. Large characters of gold announce that each monument was erected in commemoration of some distinguished person, or of some interesting event.

The police of this capital is well regulated, and the public peace seldom disturbed. At certain distances, and at the end of every cross street, is placed a soldier, who keeps watch in a sentry-box; and few streets are without a guard-house. The proprietor or inhabitant of every tenth house is, besides, held responsible for the conduct of his nine neighbours; and is bound, on the appearance of any riotous conduct, to give intimation to the nearest guard-house. The soldiers also on guard go their rounds, and at intervals strike upon a short tube of bamboo, which gives a dull hollow sound, and which, Barrow mentions, prevented himself and other members of the British embassy from sleeping until they became accustomed to it. "The city," says Sir George Staunton, "partakes of the regularity and interior safety of a camp, but is subject also to its constraints. In the suburbs only public women are registered and licensed, though they are not numerous. The inhabitants of Peking are not remarkable for their cleanliness. There are no common sewers in the city to carry off the dirt and dregs that must accumulate amid such a large collection of people; and such are the singular and revolting habits of the people, that no kind of filth or nastiness is thrown into the streets to create an offensive smell: it is carefully stored up within the house in an earthen jar kept for the purpose; and when it is full, it is sold for manure, and carried off in small bored carts with one wheel, which supply the city with vegetables. The consequence of this filthy practice is, that a disgusting odour remains about all the houses the whole day long."

The walls by which the city is surrounded do not appear to exceed twenty-five, or at most thirty feet in height. They are flanked with square towers, placed at regular distances of about seventy yards each, with a small guard-house on its summit; and these towers project about forty feet from the line of the wall. The wall at its base is about twenty-five feet thick, and the width across the top within the parapets is twelve feet. The middle part, composed of the earth which had been dug out of the ditch, is kept together by two retaining walls, partly of brick and partly of stone. No cannon are mounted on the walls or bastions; but in the high building surmounting the gate, and which is several stories in height, the port-holes are closed with red doors, on the outside of which are painted representations of cannon, not unlike the sham ports in a ship of war.

The most exaggerated ideas were formerly entertained of the population of Peking. In the last century the Jesuit Grimaldi carried it to the amount of sixteen millions. According to the most accurate information that could be obtained by the embassy of Lord Macartney, the present population of Peking may be estimated at three millions. The low houses seem to be by no means adequate to so vast a population; but very little room is required for a Chinese family, especially amongst the middling and lower classes. A Chinese dwelling, surrounded by a wall six or seven feet in height, contains a whole family of three generations, with their respective wives and children. Still, with all these allowances, it is probable that this estimate of three millions, given by the Mandarins to the British embassy, is considerably exaggerated. Long. 116. 28. E. Lat. 39. 55. N.

PELAGIANS, a Christian sect who appeared about the end of the fourth or beginning of the fifth century. They maintained that Adam was by nature mortal, and, whether he had sinned or not, would certainly have died; that the consequences of Adam's sin were confined to his own person; that new-born infants are in the same situation with Adam before the fall; that the law qualified men for the kingdom of heaven, and was founded upon equal promises with the gospel; that the general resurrection of the dead does not follow in virtue of our Saviour's resurrection; that the grace of God is given according to our merits; and that this grace is not granted for the performance of every moral act, the liberty of the will, and information in points of duty, being sufficient. The founder of this sect was Pelagius.

PELAGIUS was a native of Great Britain, but whether of England, Scotland, or Wales, is as uncertain as it is immaterial. He was born towards the close of the fourth century, and educated in the monastery of Bangor, in Wales, of which he became a monk, and afterwards abbot. In the early part of his life he passed over to France, and thence proceeded to Rome, where he had the insolence to promulgate certain opinions different from those of the church. His morals being irreproachable, he gained many disciples; and the heresy he preached made so rapid a progress, that it became necessary for the pope to exert his power. To avoid the danger, Pelagius passed over to Sicily, in the year 409, attended by his friend and pupil Celestius. In 411 they landed in Africa, continued some time at Hippo, and were present at the famous conference between the Catholics and Donatists, which was held at Carthage in 412. From thence they travelled into Egypt, and from Egypt, in 415, to Palestine, where they were graciously received by John bishop of Jerusalem. In the same year Pelagius was cited to appear before a council of seventeen bishops, held at Diospolis. They were satisfied with his creed, and absolved him of heresy. The African bishops, however, being displeased with their proceedings, appealed to the Roman pontiff, who first approved, and afterwards condemned, the opinions of Pelagius; the latter, with his pupil Celestius, was publicly excommunicated; and all the bishops who refused to subscribe the condemnation of the Pelagian heresy were immediately deprived. What became of him after this period is entirely unknown; but it seems very probable that he retired to Bangor, and died abbot of the monastery of that place. He wrote, 1. Expositionum in Epistolas Paulinas, lib. xiv.; 2. Epistola ad Demetriadem de Virginitate; 3. Explanatio Symboli ad Damasum; 4. Epistolæ ad viduam duæ; and, 5. De Libero Arbitrio. These, and many other fragments, were scattered amongst the works of St Jerome. They were also collected by Garnerius, and published in *Append. Op. Mercatoris*, p. 373.

PELAIGHE, a town of Hindustan, tributary to the Mahrattas, and situated in the province of Agra, twelve miles north from Narwar. Long. 78. 8. E. Lat. 25. 51. N.

PELANDAH, a large village of Hindustan, in the Rajpoot territories, and province of Ajmeer, said to contain 1000 houses. It is seventy miles east-south-east from Jyenagur. Long. 76. 45. E. Lat. 26. 36. N.

PELANGY, a river in the island of Magindanao, on which the capital is situated, and here as broad as the Thames at London bridge.

PELASGI, or PELASGIANS, a very ancient people, of whom the historical inquirers in the Augustan age could find no trace amongst any race then subsisting, and about whom so many opposite opinions have been confidently maintained, and so much learning unprofitably accumulated, that it is difficult, if not impossible, to arrive at any distinct or satisfactory conclusion.

Disregarding that spurious philology which raises pretensions to knowledge concerning races whose annals have long since perished, we may, however, observe, that the people known by the name of Pelasgians are supposed to have originally occupied Greece, and to have penetrated into central Italy long before the establishment of the Hellenic colonies in Magna Græcia, that is, the southern portion of the Italian peninsula. Thus much seems to be admitted on all sides, because it is borne out by the concurring testimonies of ancient authors, who are agreed in almost nothing else, respecting either the origin or the migrations of this primitive race. The questions that have been most keenly agitated amongst the learned are, whether the Pelasgians were a different nation from the Hellenes, or the same people under a different denomination; and whether they were Scythians or Goths, as Mr Pinkerton contends, or a branch of some other distinctive race of men, as others have maintained. The discussion of these matters, we are well aware, is rather a subject of antiquarian research and learned curiosity than one calculated to afford either amusement or instruction to the generality of readers; but as it has called forth displays of profound erudition, and elicited much ingenuity, a concise and comprehensive view of the actual state of the dispute may not be altogether out of place in a work which has for its object to embrace the whole cycle of human knowledge and research, even without reference to the secondary considerations of immediate interest or utility.

Mr Pinkerton, in strict accordance with his general theory, maintains that the Pelasgians were Scythians, and also that the Hellenes or Greeks were Pelasgians, or, in other words, of Scythian or Gothic origin. He argues, that as the Pelasgians certainly descended from the north-east into Greece, and thus came from, or at least through, a country which had been overspread by the Scythians long before the period of their descent into Hellas, it may be inferred that they were of the same origin and race with the inhabitants of Thrace, Thessaly, and the other countries where they first made their appearance; a conclusion, we may observe, which, whether it be well or ill founded, does not necessarily follow from the premises, because the circumstance of a roving or migratory tribe passing through a particular country in its progress towards other settlements, by no means warrants the supposition either of identity or diversity of origin with reference to the prior inhabitants of such country. Mr Pinkerton, however, contends, that at a very early period Pelasgian settlements were established on the Hellespont; that, in the days of Homer, and even much later, a district in Thessaly was named Pelasgia; that the people of Macedonia were anciently called Pelasgians; that the Thracians, who, under Eumolpus, colonized Attica, were by Herodotus denominated Pelasgians; and that Plutarch describes the same people as a roving or migratory race, who, having subdued the inhabitants, settled in the countries they had conquered,—a description which, he thinks, can only apply to the Scythians. Besides, Herodotus, Thucydides, and Strabo, all state that the Pelasgians came originally from Thessaly into Greece; and as Thessaly was anciently accounted a part of Thrace, Mr Pinkerton thence concludes that the Pelasgians were Thracians, that is, Scythians or Goths. According to him, ancient Pelasgia included Macedonia, Epirus, and afterwards the country which in later times was called Hellas or Greece; and he follows the opinion of the majority of the learned in holding that *Pelasgi* and *Hellenes* were but different names for one and the same people.

This assumed identity necessarily implies, that if the Pelasgians were Scythians or Goths, so also were the Hellenes. Mr Pinkerton, however, devotes a separate section to the discussion of this point, and accumulates a number of authorities in support of his position, that the Hellenes were Scythians. That the Hellenes were originally a small tribe in Thessaly, is, he conceives, proved by the authority of Thucydides, which is confirmed by that of Herodotus and Strabo. The same authors make it equally clear that the Thessalians were Thracians, a people who extended as far down as Phocea; whilst later authorities state, that all the people south of the Hellespont, including the Macedonians and Greeks, were of Scythian origin. Besides, the language and manners of the whole of Hellas, from Thrace to the Ionian Sea, were, according to Pinkerton, Thracian or Scythian, that is, Gothic. No ancient writer has mentioned, nor even hinted at, any diversity of speech, save as to refinement, between Peloponnesus, Attica, Epirus, Thessaly, Macedonia, and Thrace. In Homer's time the name of barbarians was not applied to the Thracians, who appear to have spoken the same language with the Hellenes; and Diodorus Siculus states that the *Scythæ Hyperborei*, or most distant Scythians, used a form of speech akin to that of Athens and Delos, in other words, Pelasgic or Gothic. Anacharsis, the Scythian philosopher, who had learned the language and studied the manners of the Greeks, pronounced them Scythian;[1] and even Xenophon bears indirect testimony to the accuracy of this judgment. The similarity between the Greek and the Gothic language is attested by Ovid;[2] and, in modern times, Salmasius, Junius, Casaubon, Ihre, Jamieson, and many other learned scholars and antiquaries, have pronounced the Greek and the Gothic to be merely dialects of the same original language, though some of them have fallen into the mistake of deriving the latter from the former. In corroboration of the same general view, Bibliander states, that in the German, which is a dialect of the Gothic, eight hundred out of two thousand radicals are common to the Greek and Latin, as well as the German; and as to the Latin, every scholar knows that, originally, it was merely the Æolic dialect of the Greek. But of all marks or proofs of the origin of nations, that of language is the most certain; and from this remarkable coincidence in radical structure, taken in connection with the other circumstances adverted to by him, Mr Pinkerton concludes, that the Pelasgians, the ancestors of the Greeks, afterwards called Hellenes, from the leader of the last tribe that arrived, were originally settled in Macedonia and Thessaly; that they were Thracians, and that the Thracians were all Scythians or Goths.

The Pelasgians or Hellenes were, according to our author, much improved by the situation of Greece, their new settlement, which, being surrounded by the sea on every side except the north, proved a centre of attraction for small colonies from Egypt and Phœnicia, countries celebrated for their early civilization. Letters were imported, tillage was introduced, and the arts of life began to be cultivated. But the colonies to which this branch of the Scythians were mainly indebted for these advantages appear to have all adopted the Pelasgic or Hellenic language, and conformed to the Pelasgic or Hellenic rites and customs; and it might even be shown that the Greek mythology was only an improved version of that which obtained in ancient Scythia, the gods being mostly deified heroes or princes. Many ideas of the Greek mythology may also be found in the Gothic, though in a form far less polished and refined. The most ancient Greek poets, it is well known, were the sole teachers of the people; they were the first who, by blending allegory with popular superstition and legendary romance, composed systems of theogony and mythology. But these early poets and teachers were all of Thrace. Linus, Orpheus, Musæus, Thamyris, and Eumolpus, were Thracians, and consequently Scythians or Goths, familiar with the ancient traditions of the race to which they belonged. This circumstance has been remarked by Eustathius, and it is certainly not a little singular, in reference to the subject before us. In a word, it appears that the Greeks originally "Scythicised," as Anacharsis called it, that is, followed the customs, manners, and traditions of the Scythians; but being improved by the introduction of foreign arts and the admixture of foreign settlers, they soon assumed a character quite distinct from that of their northern progenitors, and at length attained to the highest degree of civilization and refinement.

---

[1] Εμοι δι, φησιν ὁ Αναχαρσις, παντες Ἑλληνες Σκυθιζουσι. (Clemens Alexand. *Strom.* lib. i. p. 364.)

[2] Exercent illi *sociæ* commercia *linguæ*,
Graiaque quod Getico victa loquela sono est. (*Tristia*, lib. v. 10.)

Such is a condensed abstract of Mr Pinkerton's system, which, whether it be well founded or not, has at least the peculiar merit of being clear, distinct, and intelligible. We cannot say as much, however, for the speculations of almost any other writer who has treated of this subject, and least of all for those of Niebuhr, whose chapter on the Pelasgians is the most obscure, and therefore the least interesting, in his History of Rome. The fact seems to be, he had no settled views on the subject; and though he discusses his authorities with great ability, he has somehow failed to extract from them any definite or general results. We shall endeavour, as we best can, however, to give the reader some general notion of what this celebrated author has written respecting a race which has a double claim to attention, from its connection with the ancient history of both Greece and Italy.

According to Niebuhr, the Pelasgians were a different nation from the Hellenes, and had a language of their own, which was peculiar, and not Greek. This is his general principle, to which he repeatedly recurs, though without explaining how he arrived at such a conclusion. Yet, notwithstanding the difference here supposed, he thinks it probable that there was an essential affinity between them, from the ease with which so many Pelasgian nations ripened into Hellenes, and from the Latin containing an element which is half Greek, and admitted to have been of Pelasgic origin. But it is not easy to see how this total difference and essential affinity are to be reconciled, or how Latin could have contained an element half Greek and of Pelasgic origin, if the language of the Pelasgians was peculiar, and not Greek. Herodotus says that in process of time they came to be accounted Greeks, and that from them the Grecian theology was derived; circumstances which certainly serve to indicate the essential affinity to which Niebuhr refers. But the difficulty still remains to account for the diversity in nation and language which is predicated of the same people. It is perfectly true, as Niebuhr remarks, that the Pelasgians, in that part of history to which our monuments and traditions reach, were in a state of ruin and decay. They seemed a race that had outlived a period of other forms, looking like strangers left to languish in an altered world; and this is the reason why their history is shrouded in such obscurity. The old traditions spoke of them as a race pursued by the heavenly powers with never-ending calamities; and the traces of their abode in widely-distant regions probably gave rise to the notion that they roamed about from land to land in order to escape from these afflictions. But, surrendering to the poets the fable of their wanderings, Niebuhr thinks that he who rightly interprets the scattered hints of tradition, and searches for traces of their diffusion, will recognise in this singular people one of the very greatest nations of ancient Europe, who in the course of their migrations spread themselves almost as widely as the Celts, though in a manner still less known, and leaving even fewer memorials of their existence.

The learned historian, however, has not thought fit to apply his erudition and critical sagacity to the elucidation of this important point, which would have been a thousand times more instructive and interesting than the most elaborate discussion of authorities. He seems to have been perplexed with the discrepancies he encountered, and the difficulties with which he was beset, especially in reference to the Pelasgian tribes which originally penetrated into Italy; but having adopted no hypothesis, and hit upon no general principle, he has left the origin and history of the Pelasgians as obscure as ever; nor has he even succeeded in disentangling that part of the question which relates to their settlement in Italy, whither they are said to have carried the language of Greece in its most ancient or Æolic form. The boldness of speculation by which his disquisitions on other parts of his subject are characterized, is here altogether awanting. Instead of grappling at once with the difficulty, like Pinkerton, and thus imparting method and system to his investigations, he fritters away the whole question in detail; leaving no distinct impression on the mind, and disappointing the expectations which he had himself raised. The only leading ideas we have been able to detect are those which we have already mentioned. The important considerations of language and race enter not as elements into the investigation; and he at last concludes by reiterating the paradox with which he had commenced.

"The facility," says he, "with which they were moulded into Greeks, is a characteristic of the Pelasgian tribes, and a main cause of the dissolution and extinction of the nation. It is natural to view it as resulting from the affinity between the two races, which yet were not on that account the less essentially different; and such I believe to have been the case: yet we may observe a magical power exercised by the Greek language and national character over foreign races that came in contact with them, even where no such affinity can be conceived. The inhabitants of Asia Minor hellenized themselves from the time of the Macedonian conquest, almost without any settlements amongst them of genuine Greeks; Antioch, though the common people spoke a barbarous language, became altogether a Greek city; and the entire transformation of the Syrians was averted only by their oriental inflexibility. Even the Albanians, who have settled as colonies in modern Greece, have adopted the Romaic by the side of their own language, and in several places have forgotten the latter. It was in this way only that the immortal Suli was Greek; and the noble Hydra itself, the destruction of which we shall perhaps have to deplore, is an Albanian settlement."

This is, no doubt, very ingenious; but is it sound? To say nothing of the difficulty of conceiving the co-existence of an essential affinity with an essential difference, the cases here put are those of more refined nations in contact with such as are less so, and the consequent influence of the former upon the latter. But where is the evidence that the Greeks stood in this relation to the Pelasgians? Has it been shown by our author that the latter were really a different people from the Hellenes? Or, if so, which was the more ancient? Were there Greeks, properly so called, in Greece anterior to the arrival and settlement of the Pelasgians in that country? The latter have generally been supposed the most ancient inhabitants of the country; and it is certain that the name of Hellenes or Greeks is of later origin. The alleged facility with which the Pelasgian tribes were moulded into Greeks must therefore be explained on some principle different from that assumed by Niebuhr from inapplicable analogies. According to Pinkerton, this facility arose from the simple circumstance that the Pelasgians and Hellenes were in reality one and the same people.

(A.)

PELATÆ were those free-born citizens amongst the Athenians, who by poverty were reduced to the necessity of serving for wages. During their servitude they had no vote in the management of public affairs, from having no estate to qualify them; but this restriction was removed whenever they had released themselves from their servile situation, which they were allowed to do when able to support themselves. Whilst they continued servants, they had also a right to change their masters. We find them sometimes distinguished by the name of *Thetæ*.

PELAUDAH, a large village of Hindustan, in the Rajpoot territories, and province of Ajmeer, containing 1000 houses. It is seventy miles east-south-east from Jyenagur. Long. 76. 45. E. Lat. 26. 36. N.

PELEG, son of Eber, was born in the year of the world 1757. The Scripture says his father gave him the name of Peleg, signifying division, because in his time the earth began to be divided (Gen. xi. 16; x. 25); whether it was that Noah had begun to distribute the earth amongst his descendants, some years before the building of Babel, or that Peleg came into the world the same year that Babel was begun, and at the division of languages, or that Eber by a spirit of prophecy gave his son the name of *Peleg* some years before the tower of Babel was begun, is not absolutely certain. That which perplexes the interpreters is, that Peleg came into the world not above a century after the deluge. But it would seem, that the number of men in existence was not then sufficient for such an undertaking as that of Babel. In the next place, Joktan the brother of Peleg had already thirteen sons at the time of this dispersion, which happened after the confusion of Babel (Gen. x. 26, 27, 28). But Peleg being born in the thirty-fourth year of Eber (Gen. xi. 16), it is impossible his brother Joktan should have had such a number of children at the birth of Peleg. It would seem, therefore, that he was not born at the time of the dispersion. To this it may be answered, that Moses has there enumerated the names of the thirteen sons of Joktan (in Gen. x. 26) by way of anticipation, though they were not born until some time after the confusion at Babel; but as they possessed a very large country, it was convenient to take notice of them, and to name them amongst the other descendants of Noah, who divided the provinces of the East amongst themselves. However this may have been, at the age of thirty years Peleg begat Reu, and died at the age of 239.

PELETHITES. The Pelethites and Cherethites were famous under the reign of David. They were the most valiant men in the army of that prince, and guarded the person of the king.

PELEUS, in fabulous history, a king of Thessaly, son of Æacus, and Endeis, the daughter of Chiron. He married Thetis, one of the Nereids, and was the only mortal man who had ever married an immortal. He was concerned in the murder of his brother Phocus, and was therefore obliged to leave his father's dominions. He fled to the court of Eurytus the son of Actor, who reigned at Phthia, or, according to the opinion of Ovid, the truth of which is questioned, to Ceyx king of Trachinia. He was purified of this murder by Eurytus, with the usual ceremonies, and the king gave him his daughter Antigone in marriage. After this, when Peleus and Eurytus went to the hunting of the Caledonian boar, the father-in-law was accidentally killed by an arrow which his son-in-law had aimed at the beast. This unfortunate action obliged him to withdraw himself from the court of Phthia, and he went to Iolchos, where he was also purified of the murder of Eurytus by Acastus, the king of the country. His residence at Iolchos was short. Astydamia, the wife of Acastus, fell in love with him; but when she found him insensible to her passionate declarations, she accused him of attempts upon her virtue. The king her husband partly believed the accusations of his wife, but, not willing to violate the laws of hospitality, by putting his guest instantly to death, he ordered his officers to conduct him to Mount Pelion, on pretence of hunting, and there to tie him to a tree and leave him a prey to the wild beasts of the place. The orders of Acastus were faithfully obeyed; but Jupiter, knowing the innocence of his grandson Peleus, ordered Vulcan to set him at liberty. As soon as he had been delivered from danger, Peleus assembled his friends in order to punish the ill treatment which he had received from Acastus. He took Iolchos by force, drove the king from his possessions, and put to death the profligate Astydamia. On the death of Antigone, Peleus made love to Thetis, of whose superior charms Jupiter himself had been enamoured. His pretensions were rejected; for as he was but a mortal, the goddess fled from him with the utmost abhorrence, and, the more effectually to evade his inquiries, she generally assumed the shape of a bird, or a tree, or of a tigress. Peleus's passion was inflamed by refusal. He offered a sacrifice to the gods; and Proteus informed him, that to obtain Thetis he must surprise her whilst she was asleep in her grotto, near the shores of Thessaly. This advice was immediately attended to; and Thetis, unable to escape from the grasp of Peleus, at last consented to marry him. Their nuptials were celebrated with the greatest solemnity, all the gods attending and making them each the most valuable presents. The goddess of Discord was the only one of the deities who was absent, and she punished this seeming neglect by throwing an apple into the midst of the assembly of the gods, with the inscription of *Detur pulchriori*. The fruit of this marriage was the celebrated Achilles, whose education was early intrusted to Chiron the Centaur, and afterwards to Phœnix, the son of Amyntor. Achilles, it is well known, went to the Trojan war, at the head of his father's troops; and Peleus gloried in having a son who was superior to all the Greeks in valour and intrepidity. His death, however, was the source of great grief to Peleus; but Thetis, to comfort her husband, promised him immortality, and ordered him to retire into the grottos of the island of Leuce, where he should see and converse with the manes of his son. Peleus had by Antigone a daughter called Polydora.

PELEW ISLANDS, or PALAOS, a cluster of islands, mostly small, in the western part of the Pacific Ocean, situated between the Philippine and the Caroline Islands, and chiefly between the seventh and eighth degrees of north latitude, and the 134th and 135th of east longitude. These islands are eighteen in number, and their names are, Oroolong, Emungs, Emilleguc, Artingal, Corooraa, and Pelelew. These islands were first visited by the Spaniards from the Philippines, and received from them the appellation of the Palaos Islands, from the tall palm trees with which they are covered, and which at a distance have the appearance of ships' masts, as the term indicates. The largest of these islands is named Baubelthanap, and is about sixty miles in circumference; the smaller islands are to the south. The latter are well covered with trees of various kinds and sizes; some of them of the largest dimensions, and sufficient for forming a canoe capable of holding thirty persons. Amongst the variety of trees found here is the ebony, and a tree from which, when pierced by a gimblet, there exudes a thick white liquid of the consistence of cream. A species of tree also grows here, the sap of which blisters the skin. There is another singular tree, the branching of which is not unlike our cherry-tree; but its leaves resemble the myrtle. It has no bark, having only an outward coat about the thickness of a card, darker than the inside, though equally close in texture. It has the colour of mahogany in the interior, and is so extremely hard that no tool can work it. The other trees are the cabbage-tree, and a tree the fruit of which resembles the almond; the carimbola, and the wild bread-fruit tree; the cocoa-nut tree, the fruit of which is one of the chief articles of subsistence; and the betel-nut tree, which is in great abundance. Plantains, bananas, oranges, lemons, and sugar-canes, abound; likewise the turmeric, which the natives use as a dye, and with which they stain their skins. On none of these islands, when they were visited by the English, was there any kind of grain, or any quadruped except some brownish-gray rats, which ran wild in the woods, and a few lean cats, which were seen in some of the houses, and had probably escaped to the shore from some wreck or drift-wood. The common domestic fowls, such as cocks and hens, abound in the woods, though they are not domesticated; and, previous to the arrival of the English, they were not used for food by the natives, who reared pigeons for this purpose. Along the shores fish in great variety are found, with many shell-fish, particularly the large Kima cockle, which they procure by diving, and which, like other barbarous nations, they eat raw. Many of the other birds are distinguished alike by the beauty of their plumage and the variety and melody of their notes. There were several small birds of very melodious notes, especially one whose notes resembled those of a flageolet, and which sings morning and evening.

These islands, when seen from the sea, appear of a rugged mountainous aspect, and covered with wood; the interior parts being mountainous, and the valleys extensive and beautiful, opening into prospects of picturesque beauty. A reef of coral surrounds the shore, which is about five or six leagues broad, and in no case less than three. The soil is in general rich, and produces luxuriant herbage, which, as there is no cattle to eat it, grows high, and is scorched and burned with the heat of the sun. The climate, as in all tropical countries, is divided into the two seasons, the wet and the dry. There is nothing in these islands which deserves the name of a river; and the inhabitants derive their supplies of fresh water from small rivulets and ponds.

From the accounts given of these islands by Captain Wilson, commander of the Antelope packet, in the service of the East India Company, who was wrecked on them, and by other navigators, the inhabitants appear to have made but little progress in civilization. They are not, indeed, as they had been represented, irreclaimable savages, inhuman and barbarous, and feeding on human flesh; but, on the contrary, hospitable, friendly, and humane in their dispositions, though ignorant of the arts and manners of civilized life. They are, however, industrious, and every part of the island bears marks of cultivation. Yams and cocoa-nuts are the chief articles of subsistence, and to the rearing of these their attention was chiefly directed. They are a stout and well-made people, rather above the middle stature; and their complexions are not black, though of a deeper shade than the Indian copper-colour. They have long flowing hair, rather disposed to curl, which they form into one large loose coil round their heads. Some of the women, who have remarkably long hair, allow it to hang down their backs. The men go entirely naked; the women wear a slight covering of two little aprons, or rather thick fringes, one before and one behind, about ten inches deep and seven wide; these are made of the husks of the cocoa-nut, stripped into narrow slips, and dyed with different shades of yellow. Both men and women have the savage practice of tattooing, which operation takes place when both sexes arrive at maturity. One ear of the men is bored, and in the women both ears, and beads are worn in the perforated ear by the men; but the women put some leaf through, or an ear-ring of tortoise-shell inlaid. They also perforate the cartilage between the nostrils in both sexes, through which they frequently put a little sprig or blossom of some plant or shrub that pleases their fancy. Like most barbarous nations, both sexes are expert swimmers, and appear to be as perfectly at ease in the water as on land. In diving their skill is also remarkable; and the men, if they saw any thing at the bottom of the sea which attracted their attention, would instantly jump overboard and bring it up. They mix no salt nor any other seasoning in any thing they eat; and the milk of the cocoa-nut forms their usual beverage. They had no method of measuring time but by the height of the sun, though they had some knowledge of the stars, having names for several of them, which they pointed out to their English visitors. Their houses were of a rude construction. They were raised about three feet from the ground, and placed on large thick and oblong stones, as if cut from the quarry. Their fishing-tackle was, however, well manufactured. The hooks were made of tortoise-shell; and their twine, their cord, and all their fishing-nets, were well manufactured from the husks of the cocoa-nut. They form the mats on which they sleep, and which they throw over them when at rest, out of the plantain leaf. They use the plantain leaf at their meals instead of a plate; the shell of the cocoa-nut they polish very nicely, and it serves them as a cup to drink out of. Their best knives are made of a piece of mother-of-pearl oyster-shell. They make vessels of earthen ware, in which they boil their fish and yams; and their hatchets are made of the Kima cockle ground to a sharp edge. Their principal weapons are spears twelve feet long, made of bamboo, pointed with some hard wood, and darts and slings. They carry on a maritime warfare with each other in canoes, which they make from the trunk of a tree, with an outrigger, and furnished with lateen sails made of mattine.

The government of these islands is monarchical. The king has the supreme authority, and, though divested of all external decorations of royalty, he is honoured with every mark of personal distinction. The nobles approach him with the greatest respect; and his common subjects, whenever they pass him, or have occasion to address him, use every mark of the meanest servility, crouching towards the ground in his presence, or even before any place where he is supposed to be. The officer who approaches nearest to the king in power is his brother, who is generalissimo of all the forces. The king is always attended by a particular officer, who does not appear to possess any hereditary, but rather a delegated authority. He is first consulted in all public affairs, and has other marks of high dignity; but whether his office and character were religious or civil, the English could not exactly learn. Polygamy prevails in these islands, but in general the natives have not more than two wives, though the king had five, who lived in separate dwellings. They have little or no religion, and no outward observances that the English could perceive whilst they resided amongst them. The king became much attached to the English who were shipwrecked on these islands, and showed them great kindness. Indeed, so highly did he esteem Captain Wilson, that he intrusted his second son, Prince Lee Boo, to his care, to accompany him to England. This young prince was of the most amiable dispositions, anxiously desirous of knowledge, and capable of receiving it. He died of the small-pox, at Captain Wilson's house in London, in 1784, at the age of about twenty years. In return for the kindness shown by Abba Thulle, the prince of Pelew, to the crew of the Antelope wrecked on the island of Oroolong in 1783, the East India Company sent him, in the year 1791, a present of four young cows in calf, two young bulls from Sebojee, and ten ewes and two rams of the Bengal breed, eight she-goats and two rams of the Surat breed, with sows, boars, geese, ducks, hens, and turtle-doves, besides European swords and hardware, arms, and ammunition. In 1791, the captain of the Panther, a Bombay cruizer, was so much pleased

Pelicondah
||
Pelletier.

with the manners of the natives, that he resigned his command, with a view of spending the remainder of his days amongst them. But he soon wearied of being amongst savages, and returned in his pinnace to Macao. Several Europeans have been in the habit of residing here for the purpose of collecting biche de mer, tortoise-shell, and shark fins, for the China market. The Jesuits of Manilla, in the Philippines, endeavoured, in 1696, to reduce these islands, and effected a landing in 1710. But those who landed were never more heard of; and the ship from which they disembarked, after waiting long for them in vain, was at length compelled to depart, and to leave them on the island. Long. between 134. 5. and 134. 40. E. Lat. between 6. 54. and 8. 12. N.

PELIAS, in fabulous history, the twin-brother of Neleus, was son of Neptune by Tyro, daughter of Salmoneus. His birth was concealed by his mother, who wished her father to remain ignorant of her incontinence. He was exposed in the woods, but his life was preserved by shepherds; and he received the name of Pelias, from a spot of the colour of lead in his face. Some time afterwards Tyro married Cretheus, son of Æolus, king of Iolchos, and became mother of three children, of whom Æson was the eldest. Pelias visited his mother, and was received into her family; but after the death of Cretheus, he unjustly seized the kingdom, which belonged to the children of Tyro by the deceased king. In order to strengthen himself in his usurpation, Pelias consulted the oracle; and when he was told to beware of one of the descendants of Æolus, who should come to his court with the one foot shod and the other bare, he privately removed the son of Æson, after he had openly declared that he was dead. But these precautions proved vain. Jason, the son of Æson, who had been educated by Chiron, returned to Iolchos when come to years of maturity; and having lost one of his shoes in crossing the river Anaurus or Evenus, Pelias immediately perceived that this was the person whom he had so much dreaded. His unpopularity prevented him from acting with violence to a stranger, whose uncommon dress and commanding aspect had raised admiration in the people. But his astonishment was greatly excited when he saw Jason arrive at his palace, with his friends and relations, and boldly demand the kingdom which he had usurped. Pelias, conscious that Jason's complaints were well founded, endeavoured to divert his attention, and told him that he would voluntarily resign the crown to him, if he should proceed to Colchis in order to avenge the death of Phryxus, the son of Athamas, whom Æeres had cruelly murdered. He further declared, that the expedition would be attended with the greatest glory, and that nothing but the infirmities of old age could prevent himself from vindicating the honour of his country, and the injuries of his family, by punishing the assassin. This proposal, so warmly recommended, was with equal warmth accepted by the young hero, and his intended expedition was made known all over Greece. Whilst Jason was absent on the Argonautic expedition, Pelias murdered Æson and all his family; but, according to the more received opinion, Æson was still living when the Argonauts returned, and he was restored to the flower of youth by the magic of Medea. This change in the vigour and constitution of Æson astonished all the inhabitants of Iolchos; and the daughters of Pelias, who have received the patronymic of Peliades, expressed their desire to see their father's infirmities vanish by the same powerful magic. Medea, who wished to avenge the injuries which her husband Jason had received from Pelias, raised the desires of the Peliades, by cutting an old ram to pieces, boiling the flesh in a cauldron, and then turning it into a fine young lamb. Having witnessed this successful experiment, the Peliades cut their father's body to pieces, after they had drawn all the blood from his veins, on the assurance that Medea would replenish them by her wonderful power. The limbs were immediately put into a cauldron of boiling water; but Medea, suffering the flesh to be totally consumed, refused to give the promised assistance, and the bones of Pelias did not even receive the honours of sepulture. The Peliades were four in number, Alceste, Pisidice, Pelopea, and Hippothoe, to whom Hyginus adds Medusa. Their mother's name was Anaxibia, the daughter of Bias or Philomache, the daughter of Amphion. After this parricide, the Peliades fled to the court of Admetus, where Acastus, the son-in-law of Pelias, pursued them, and made their protector prisoner. The Peliades died and were buried in Arcadia.

PELICONDAH, a town of Hindustan, in the province of the Circars, and district of Cicacole. Long. 84. 10. E. Lat. 18. 33. N.

PELIME, a river of Asiatic Russia, which falls into the Taudo, near the town of the same name.

PELING, an island in the Yellow Sea, near the coast of Corea, ten miles in length and four in breadth. Long. 124. 28. E. Lat. 38. 24. N.

PELING *Isle*, an island in the Eastern Seas, near the east coast of the island of Celebes, between the 123d and 124th degrees of east longitude. It is fifty miles in length by fifteen in breadth, and is surrounded by many smaller isles, with numerous rocks and shoals. Long. 124. 28. E. Lat. 38. 24. N.

PELION, a mountain of Thessaly, near Ossa. It rises majestically over the Sinus Pelasgicus, having its top covered with pines, and its sides with oaks. From this mountain was cut the spear of Achilles, called *pelias*, which none but himself could wield.

PELLA, in *Ancient Geography*, a town situated on the confines of Emathia, a district of Macedonia. It was the royal residence, and being situated on an eminence verging to the south-west, was encompassed with impassable marshes summer and winter.

PELLETIER, BERTRAND, a celebrated chemical philosopher, was born at Bayonne in the year 1761. He very soon discovered a strong predilection for the sciences, to cherish which he had every thing in his father's house that could reasonably be desired, and there acquired the elements of that art for which he was afterwards so famous. His subsequent progress took place under Darcet, who admitted him amongst the pupils attached to the chemical laboratory of France. Five years of intense application under such a master gave him a stock of knowledge very uncommon at his years. As a convincing proof of this, when only twenty-one years of age, he published a number of valuable observations on arsenic acid; proving, contrary to the opinion of Macquer, that sulphuric acid distilled from the arseniate of potash disengages the acid of arsenic.

Encouraged by the success which had attended his first chemical labours, he communicated his remarks on the crystallization of sulphur, cinnabar, and the deliquescent salts; as also the examination of zeolites, particularly the false zeolite of Freyburg, which he discovered to be merely an ore of zinc. He likewise made observations on the oxygenated muriatic acid, in reference to the absorption of oxygen; on the formation of other acids, chiefly the muriatic and the acetous; and a number of memoirs on the operation of phosphorus made in the large way, its conversion into phosphoric acid, and its combination with sulphur and most metallic substances.

It was by his operations on phosphorus that he burned himself so severely as nearly to endanger his life. Immediately on his recovery he began the analysis of different varieties of plumbago from France, England, Germany, Spain, and America, and gave both novelty and interest to his work, even after the labours of Scheele on the same subject had made their appearance. The analysis of carbonate of barytes led him to make experiments upon animals, from which he discovered that this earth is a real poison, in whatever way it be administered. Strontites was also analysed by this celebrated chemist, and found to contain a new earth.

Pelletier discovered a process for preparing verditer in the large way, equal, it is said, in beauty to that which is manufactured in England. He was likewise amongst the first who showed the possibility of refining bell-metal, and separating the tin. His first experiments were performed at Paris, after which he went to the foundery at Romilly to prove their accuracy in the large way. He was soon after this admitted a member of the Academy of Sciences at Paris, and subsequently accompanied Borda and General Daboville to La Fère, to assist in experiments upon a new species of gunpowder. Being obliged to pass great part of the day in the open air during a cold and moist season, in order to render his experiments more decisive, his health, which was naturally delicate, became very much impaired. He partly recovered it, but again fell a victim to his thirst of knowledge; for he was at one time nearly destroyed by inspiring the oxygenated muriatic acid gas, which occasioned a convulsive asthma, that at times appeared to abate, but was found to be incurable. The assistance of art was insufficient to save him, and he died at Paris on the 21st of July 1797, of a pulmonary consumption, in the flower of his age, being only thirty-six.

PELLEW, SIR EDWARD'S GROUP, a cluster of islands on the north coast of New Holland, which occupy a space of thirty-four miles east and west, by twenty-two north and south, on the western coast of the Gulf of Carpentaria. These islands are far from being fertile, and when the surface is not bare rock, it consists of sand, with a greater or less proportion of vegetable soil. The larger islands are covered with trees, bushes, and grass. In the large islands traces of the kangaroo are to be seen, and turtle-tracks on the beaches. Their names are Vanderlin's Island, North-west, South-west, and Centre Islands. The latitude of Centre Island is 15. 39. S.

PELLISSON, or PELLISSON FONTANIER, PAUL, was the son of James Pellisson, counsellor at Castres. He was born at Beziers in 1624, and educated in the Protestant religion. He studied with success the Latin, Greek, French, Spanish, and Italian tongues, and applied himself to the perusal of the best authors in these languages; after which he studied with reputation the law at Castres. In 1652 he purchased the post of secretary to the king, and five years afterwards became first deputy to M. Fouquet. He suffered by the disgrace of that minister; and in 1661 was confined in the Bastille, whence he was not discharged till four years afterwards. During his confinement he applied himself to the study of controversy; and in 1670 he abjured the Protestant religion. Louis XIV. bestowed upon him an annual pension of two thousand crowns, and he likewise enjoyed several posts. In 1676 he received the abbey of Giment, and some years afterwards the priory of St Orens at Auch. He died in 1693. His principal works are, 1. The History of the French Academy; 2. Reflections on religious Disputes, in four vols. 12mo; 3. The History of Louis XIV.; and, 4. Historical Letters and Miscellanies, in three vols. 12mo.

PELOPIA, a festival observed by the Eleans in honour of Pelops. A ram was sacrificed on the occasion; but priests and people were both prohibited from partaking of it, on pain of excommunication from Jupiter's temple; the neck only being allotted to the officer who provided wood for the sacrifice. This officer was called Ξυλευς; and white poplar was the only wood made use of at this solemnity.

PELOPONNESUS, a large peninsula to the south of the continent of Greece. It was called the island of Pelops, though properly not an island, but a peninsula, ending in a point like the leaf of the plane-tree. Anciently called *Apia* and *Pelasgia*, this peninsula was second to no other country for nobleness, being situated between the Ægean and Ionian Seas, and resembling a plane-leaf, on account of its angular recesses or bays. It is now called the Morea.

PELOPS, in fabulous history, the son of Tantalus, king of Phrygia, went into Elis, where he married Hippodamia the daughter of Œnomaus, king of that country, and became so powerful, that all the territory which lies beyond the isthmus, and composes a considerable part of Greece, was called *Peloponnesus*, from his name Pelops, and the Greek word νησος, an island.

PELTA, a small, light, manageable buckler, used by the ancients, and also worn by the Amazons. The *pelta* is said by some to have resembled an ivy leaf in form; by others it is compared to the leaf of an Indian fig-tree, and by Serbius to the moon in her first quarter.

PELUSSIN, a town of France, in the department of the Loire, and arrondissement of St Etienne. It has some considerable manufactories of silk; and the neighbourhood is remarkable for the great quantity of chestnuts which are collected annually for exportation. It contains about 460 houses, with 3350 inhabitants.

PELUSIUM, in *Ancient Geography*, was a strong city of Egypt, without the Delta, distant twenty stadia from the sea, and situated amidst marshes, from which circumstance it derived its name. It was called the *key* or *inlet of Egypt*, because, if taken, the rest of Egypt lay quite open and exposed to an enemy.

PEMBA, a low, well-wooded, and extremely fertile island, fourteen leagues in length, near the eastern coast of Africa. It exports both corn and cattle to a considerable amount. Long. 41. E. Lat. 5. S.

PEMBERTON, a township of the parish of Wigan, in the hundred of West Derby, in the county of Lancaster, 198 miles from London. It has no market, and is chiefly inhabited by manufacturers. The population amounted in 1801 to 2309, in 1811 to 2934, in 1821 to 3679, and in 1831 to 4277.

PEMBROKE, the county-town of the shire of that name, in South Wales, situated on a branch of the fine haven of Milford. It is 250 miles from London, and ten from Haverford West. It is a very ancient town, and was once defended by strong walls and a powerful castle, the ruins of which still remain. It consists of one long street, rising up to the remains of the castle, which has an imposing aspect. There are two churches, St Mary's and St Michael's, the latter of which is of a remote age. The county assizes and elections are held here; and there is a tolerable market, which is held on Saturday, but little trade of any kind. In virtue of the municipal reform law passed in 1835, the town elects annually a corporation, consisting of a mayor, six aldermen, and eighteen councillors, with justices of the peace nominated by the crown; for which purpose it is divided into two wards. The population amounted in 1801 to 2595, in 1811 to 2525, in 1821 to 4925, and in 1831 to 6511.

PEMBROKESHIRE is a maritime county of South Wales. It forms a peninsula at the south-west corner of the principality, and is surrounded by the sea everywhere except on the eastern side, where it is bounded by Carmarthenshire and by Cardiganshire. Its shape is very irregular, which makes it difficult to ascertain its exact extent. Its extreme length is thirty, and its extreme breadth twenty-seven miles. Its area is estimated, but with no decided accuracy, at 575 square miles.

It is generally an undulating county, composed of plains, with hills of no great elevation, except in the northern part, where a range of mountains is stretched out to the extent of nine or ten miles. The loftiest points of this group are Precelly Top, 1754 feet, and Brennin-Vaur, 1285 feet above the level of the sea. Few of the hills in the other parts of the county attain a greater height than 290 feet. As the greater part of the country is destitute of woods, it has a bare and bleak appearance, except in the valleys, where the numerous brooks which flow through them impart a pleasing verdure to the bordering meadows.

The most considerable rivers are the Eastern Cleddaus, which forms at first the dividing line between this county and Carmarthenshire; and the Western Cleddaus, which traverses a considerable portion of Pembrokeshire. These two rivers unite, and form the admirable estuary of Milford Haven, which is considered as the best harbour in the British islands. It is sufficiently capacious to contain the whole navy of England, is so completely sheltered as to be secure from all winds, and has good holding ground, with competent depth of water. During the war these advantages induced the lords of the admiralty to establish a dock-yard, chiefly with the view of building ships. It is situated on the southern shore of Milford Haven, about two miles from the town of Pembroke. It includes an area of about sixty acres, its surface descending in a gradual slope to the water's edge, along the shore of which there is ample space for a couple of dry docks, and at least twelve building slips. The work has been executed with care and accuracy; but, owing to the state of general tranquillity which has prevailed for more than twenty years, it is not of the vast importance that it may become in case of another extended naval war. When at its greatest height, this establishment had about five hundred men. The town of Huberstone, on this bay, is now the resort of the packet for the south of Ireland, and is thus a place of much activity, as far as regards the number of passengers to and fro. The entrance to this important estuary is almost free from danger; the principal difficulty is a sunken rock called the Chapel Rock, but it may easily be avoided, and has at low tide seventeen feet of water on it. This rock, as well as the shoals near it, is well buoyed. There are several bays on this coast, in which are good anchorage and safe riding for ships. The most important of these are St Bride's Bay, Ramsey Sound, and Nayland Road.

The rivers of this county are but of short course, and, with the exception of those two which empty themselves into Milford Haven, discharge but little water. The names of these rivers are the Newgall, the Solva, the Alan, the Gwayn, the Nevern, the Cuch, and the Tivy.

The soil of the county is generally a red loam, in many parts resting on a calcareous subsoil, and admirably adapted for the growth of corn. In some places the surface is covered with porous stones, which are supposed to imbibe and retain the salt from the saline air, and to render the land highly prolific. The principal grain consists of wheat, barley, and oats; but in some parts of the county rye is extensively cultivated. The modes of cultivation are commonly the same as those which prevailed in remote ages, that is, growing wheat, barley, and oats in succession, till the land was so exhausted as to yield no increase, when it was suffered to return to its natural state, under the idea of recovering itself by rest. Very little attention is paid to the preservation of manure; the barns and farming erections are very badly constructed; and the agricultural implements, especially the ploughs, are of a rude and antique form. Such is the description of the greater part of the agricultural state of the country; but there are splendid exceptions. The size of the farms varies from fifty to a hundred acres; but the average extent of them is estimated to be about two hundred. Some of the occupiers are annual tenants, but many hold from the lords of manors by leases for three lives at an agreed rent, though without any fine on the renewal of a life, as is customary in England, and on the lands in Pembrokeshire belonging to the church.

The black cattle of this county are of an excellent race, and are annually distributed over the south of England in droves, which travel from fair to fair till the whole are sold. They are commonly sent to market when they are in calf for the first time. Some valuable horses are bred here. The sheep are small, and yield little wool, but the mutton is very highly esteemed.

At no very remote period silver was found in the parish of St Elwys, or St Bride's Bay. The mine, which was discontinued in the reign of Queen Elizabeth, was resumed some years ago, but not with such success as to induce perseverance. Some excellent lead ore is found upon the banks of the Tivy, but the mines are not worked with any degree of spirit. The most important production of the mines is coal. It is confined to a district of narrow extent on the southern side of the county. The strata lie near the surface, and the quality is not very good. The inhabitants use the small coal mixed with clay and formed into balls; it is sulphureous, and highly offensive to strangers.

The manufactures of this county are exceedingly few, but the building of ships and boats gives employment to about 400 persons. There are about 130 weavers of woollen cloth and flannels; but they are so much scattered about the county, that the largest number in any one place is no more than seventeen at St David's. Attempts have been made to introduce cotton-spinning, but without success. The chief trade now consists in the conveyance of coals from Tenby to the opposite shore of Devon, Cornwall, and Somerset, where they are found fitter for lime-burners and maltsters than for fuel in dwellings. The great travelling causes the circulation of much money, and some is derived from the company that in the summer frequent Tenby for the purpose of sea-bathing.

The inhabitants are of two distinct races. If a line be drawn through the whole county, bisecting the town of Haverford West, it will be found that on one side of the line nothing but English is spoken, and on the other side only Welsh. This is so definite, that in the town of Haverford West the one language is spoken in the upper, and the other in the lower part of it; and there are two markets, one frequented by the English, the other by the Welsh peasantry. The part where the English live, commonly called Little England beyond Wales, was originally peopled by a colony of Flemings, who have kept themselves distinct since the first colonization. It is admitted that they speak the English language with more purity than the lower classes in any other part of the island.

One member of parliament is chosen by the freeholders for the county, and the polling-places are Haverford West, Pembroke, Narberth, Fishguard, Newport, Tenby, and Mathry. The towns of Milford, Pembroke, Tenby, and the ancient borough of Wiston, elect one member amongst them.

St David's, the see of a bishop, is a miserable collection of cottages, in the midst of traces of ancient, extensive, and numerous buildings. The object deserving of most notice is the cathedral, the antiquity of which is very great, having been originally built about the year 1180, and enlarged in 1280 and 1328. The bishop's palace is a magnificent pile, not far from the cathedral, on the opposite side of the river Alan. It was originally a quadrangular building of great extent, of which at present only one side remains entire.

Amongst the ancient buildings in this county, the most remarkable are Carew Castle, on a creek of Milford Haven; Manorbeer, the mansion of the Barry family, of which Giraldus Cambrensis was a member; and Killgarran, on the river Tivy, the massy towers and fragmented bastions of which present a most imposing spectacle.

The picturesque beauties of this county, the mildness of the air, and the abundance of every thing, have induced many gentlemen to select it as the place of their residence. The houses of this description are therefore too numerous to be mentioned; but amongst the more ancient proprietors who have splendid seats are, Lord Milford, Sir John Owen, Lord Kensington, Lord Cawdor, and several others.

The population of the county amounted in 1801 to 56,280, in 1811 to 60,615, in 1821 to 74,009, and in 1831 to 80,900. The annual value of the real property, as assessed in 1815 for the property tax, was L.219,589.

According to the returns of the year 1831, the families chiefly employed in agriculture were 7974; those chiefly employed in trade, manufactures, and handicraft, were 4510; and those comprised in neither of the preceding classes were 4102. The number of males under twenty years of age was 18,356. The occupiers employing labourers were 1842, and the occupiers not employing labourers were 1864. The labourers employed in agriculture were 6075. Persons employed in manufactures or manufacturing machinery were 131; those employed in retail trade, or in handicraft, or masters, or as workmen, 4785; capitalists, bankers, professional and other educated men, 605; labourers employed in labour not agricultural, 1599; other males under twenty years of age (except servants), 1124; male servants, twenty years of age, 331; male servants under twenty years of age, 219; female servants under twenty years of age, 4929. The towns and their population which exceed 2000 persons are, Pembroke, 6511; Haverford West, 3915; Narberth, 2589; St David's (city), 2388; Tenby, 2128; and Dogmels, 2109.

PEMGUR, a town of Hindustan, in the province of Khandeish, belonging to the Mahrattas, on the southern bank of the Nerbuddah, seventy-three miles south-east from Oojain. Long. 76. 35. E. Lat. 22. 28. N.

PEMNAGUR, a town of Hindustan, in the province of Bahar, and district of Tirhoot. It formerly possessed a strong fort, surrounded by a thick wood. Long. 85. 43. E. Lat. 26. 29. N.

PEN, a little instrument, usually formed of a quill, and serving to write withal. But pens are sometimes made of silver, brass, or iron.

Dutch Pens are made of quills which have passed through hot ashes, to take off the grosser fat and moisture, and render them more transparent.

Fountain Pen is a pen of silver, brass, or other metal, so contrived as to contain a considerable quantity of ink, and let it flow out by degrees, to supply the writer a long time without his being under the necessity of taking fresh ink.

The *Geometric Pen* is an instrument by which a right line, a circle, an ellipse, and other mathematical figures, may be described by a circular motion. It was first invented and explained by Suardi, in a work entitled *Nuovo Instromento per la Descrizzione di diverse Curve antiche e moderne.* Several writers had observed the curves arising from the compound motion of two circles, one moving round the other; but Suardi first realized the principle, and reduced it to practice.

PENAFIEL, a town of the province of Toro, in Spain, the capital of a partida of the same name. It is situated on the river Duraton, and has a citadel, four churches, two monasteries, and 650 houses, with 3400 inhabitants.

PENANCE, a punishment, either voluntary or imposed by authority, for the faults which a person has committed. Penance is one of the seven sacraments of the Catholic church. Besides fasting, alms, abstinence, and the like, which are the general conditions of penance, there are others of a more particular kind; as the repeating a certain number of ave-marias, pater-nosters, and credos, wearing a hair-shirt, and giving one's self a certain number of stripes.

PENARANDA, a town of Spain, in the province of Avela, and partida of St Jago. It is the capital of a small district called the Sermo de St Vincente. It was once fortified, but its walls are now in a dilapidated state. It has a fortress, three churches, two monasteries, nine hundred and fifty houses, and about 3500 inhabitants, depending for a scanty subsistence chiefly on the cultivation of the soil.

PENATES, in Roman antiquity, were a kind of tutelar deities, either of countries or particular houses, in which last sense they differed in nothing from the lares. The penates were properly the tutelar gods of the Trojans, and were only adopted by the Romans, who gave them the title by which they are here described.

PENCIL, an instrument used by painters for laying on their colours. Pencils are of various kinds, and made of various materials. The largest sorts are made of boars' bristles, the thick ends of which are bound to a stick, larger or smaller, according to the uses they are designed for. The finer sorts of pencils are made of camels', badgers', and squirrels' hair, and of the down of swans, which are tied at the upper end with a piece of strong thread, and enclosed in the barrel of a quill.

Pencil is also an instrument used in drawing or writing. It is made of long pieces of black lead or red chalk, placed in a groove cut in a slip of cedar; upon which other pieces of cedar being glued, the whole is planed round, and one of the ends being cut to a point, it is fit for use.

PENDANT, an ornament hanging at the ear, and frequently composed of diamonds, pearls, or other jewels.

Pendants, in *Heraldry*, parts hanging down from the label to the number of three, four, five, or six at most, resembling the drops in the Doric frize. When they are more than three, they must be specified in blazoning.

Pendants of a Ship are those streamers, or long colours, which are split and divided into two parts, ending in points, and suspended at the heads of masts, or at the yard-arm ends.

PENDLETON, a township in the parish of Eccles and hundred of Salford, in the county of Lancaster, a hundred and eighty-eight miles from London and three from Manchester. It has no market, and is chiefly inhabited by manufacturers of cotton goods. The population amounted in 1801 to 3611, in 1811 to 4805, in 1821 to 5948, and in 1831 to 8435.

PENDULUM.

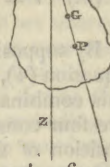
Pendulum.

When a solid and heavy body of any form and description is suspended from an axis fixed horizontally, and round which it can turn with freedom, or at least with a very slight degree of friction; if we withdraw it, however little, from the position of equilibrium at which it naturally places itself when at rest, and then abandon it to itself, the force of gravity, which is now no more destroyed by the resistance of the axis of suspension, brings back the body towards its primitive position of equilibrium with a velocity continually accelerated. When it reaches this position, the accelerating force ceases for a moment to act on it, but the body, continuing to move in consequence of the velocity already acquired, rises on the other side of the vertical line, and continues rising until the constantly increasing force of gravity destroys its velocity—then it stops for an instant, and again yielding to the continued action of gravity, to which there is now no more opposition, it again falls with a motion exactly similar to that which it had when it began to descend from the opposite side of the vertical. It returns then, in the same manner, to its primitive position of equilibrium, passes it, and re-ascends on the opposite side of the vertical, to the point where its velocity is destroyed anew; after which it again begins to descend, and again to remount; and the oscillatory motion which results from these alternations only ceases in consequence of the resistance of the air and the friction of the axis, which gradually reduce it to nothing.

An apparatus of this kind is termed a *pendulum.* The oscillations of pendulums can be calculated completely, and with perfect rigour, by the principles of mechanics, when they are supposed to take place in a vacuum, and round an axis, which presents no friction. The results in regard to this imaginary case are so much the more important to be known, as in the real experiments we always endeavour to approach it as near as possible, by combining to the utmost every circumstance which can tend to prolong the duration of the pendulum's motion. These are the results, then, which it is proper to present first in order, as they exhibit a first approximation to every motion of this kind which can be realized.

In this simple case, whatever be the form of the body which constitutes the pendulum, provided that it remains invariably constant, all the successive oscillations have equal amplitudes, and are also of equal duration among themselves, so that the motion, once begun, never ceases to go on. In the case of oscillations with different amplitudes, the duration is in general unequal; but this inequality diminishes in proportion as the amplitudes become less, and it ceases altogether at the limit where they become infinitely small; so that all the oscillations made with amplitudes, which, in a physical sense, may be reckoned infinitely small, are sensibly of equal duration.

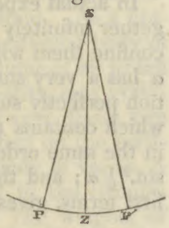
Fig. 1.



In regard to the nature of the motion in each oscillation, it is absolutely the same for every body, whatever be its form; and we may always consider it as identical with that of a pendulum formed by a material gravitating point suspended at the extremity of a thread, supposed to be inflexible and without weight. Let l denote the ideal length of such a pendulum, which is called a *simple pendulum.* Let m be the mass of an oscillating body (fig. 1) with which we wish to compare it, and which we shall call, in opposition to the other, a *compound pendulum.* From the centre of gravity of this body, denoted by G, conceive a perpendicular SG drawn to the axis of suspension, and call h the length of this line. If we multiply each element of the mass m by the square of its distance from the same axis, and denote the sum of the whole by c, the product c thus formed will be what is called in mechanics the momentum of inertia of the body m relatively to the axis in question. In order that the motion of the simple pendulum SP be exactly isochronous with that of the body m, it is sufficient that we have the equation $l = \frac{c}{mh}$; and, besides this, that the lines SP and SG have at any one instant equal angular velocities at the same distance from the vertical. This last condition will be fulfilled if, for example, at the beginning of the motion the lines SP, SG are equally distant from the vertical, and that the simple and compound pendulum be then abandoned together to the action of gravity, or be driven with equal velocities in the plane of their oscillations. The simple pendulum will then accompany the compound one in all its successive excursions, and its direction will always coincide with the line SG drawn from the centre of gravity of the body m, perpendicular to the axis of suspension. The length l being ascertained by this formula, we can lay it off on the line SG, setting out from the axis of suspension S; and the point P, where it terminates, is called the *centre of oscillation* of the body m.

The initial conditions above stated can always be established, and the analytical value of l is also always real. For every given compound pendulum, then, we can always assign a simple pendulum, which is isochronous with it, and of which the motion is absolutely similar to that of the line SG. By means of this substitution, we have nothing more to consider or to compare, but the different lengths of the simple pendulums, and it then only remains to ascertain the mode in which such pendulums perform their oscillations.

Fig. 2.



To do this in the simplest manner possible, let us conceive that the arc ZP (fig. 2) is half the extent of the oscillations through the vertical SZ, and suppose that the pendulum arrived or placed in this position is there abandoned to the sole action of gravity without any initial velocity of impulsion. Call α the angle PSZ, and denote by g the intensity of gravity measured by the double of the space which heavy bodies describe at the place where the experiment is made, when they fall freely in a right line during the unity of time. Then denoting always by l the length of a simple pendulum SP or SZ, the time T of its whole oscillation in the arc PZP′ or PP′ will be expressed by the following series:

$$(1.)\ \mathrm{T} = \pi\sqrt{\frac{l}{g}}\left\{1 + \left(\tfrac{1}{2}\right)^2 \sin.^2 \tfrac{1}{2}\alpha + \left(\frac{1\cdot3}{2\cdot4}\right)^2 \sin.^4 \tfrac{1}{2}\alpha + \left(\frac{1\cdot3\cdot5}{2\cdot4\cdot6}\right)^2 \sin.^6 \tfrac{1}{2}\alpha +, \&c.\right\},$$

π being the ratio of the circumference of the circle to its diameter, or 3·14159.

If, besides, we denote the velocity of the pendulum in any point of its oscillation by V, θ being its angular distance from the vertical, we have

$$(2.)\ \mathrm{V}^2 = 2gl(\cos.\theta - \cos.\alpha),$$

or, what comes to the same thing,

$$\mathrm{V}^2 = 4gl \sin.\tfrac{1}{2}(\alpha + \theta) \sin.\tfrac{1}{2}(\alpha - \theta).$$

These formulæ will still serve if the pendulum, instead of falling freely from the extremity of the arc, receives there an initial velocity expressed by V′, provided always this velocity is within the limits which permit the oscillatory motion to take place. If this be the case, indeed, it will be sufficient to consider the pendulum as setting out with an initial impulse from another angular distance, α'. Then it will be necessary that this unknown distance α' satisfy, instead of α, the general equation of the velocities, and that α becomes in it θ, which gives

$$(3.)\ V'^2 = 2gl\{\cos.\alpha - \cos.\alpha\}.$$

The half amplitude α' of the oscillations being the only unknown quantity in this equation, will be thus determined, and their duration will be then obtained by the equation (1), but putting in it α' instead of α. This same substitution made in the equation (2) will give

$$V^2 = 2gl(\cos.\theta - \cos.\alpha')$$

for the velocity in any point whatever of the oscillation. But these transformations are only possible when the equation (3) gives for α' a real arc, and consequently for cos. α' a value comprehended between + 1 and — 1. We may easily conceive, that, when the cos. α' exceeds these limits, it is because the velocity of impulse V′ exceeds the greatest velocity of the fall which the pendulum can acquire in a circle of a radius l, even supposing it to fall from the very summit. It is evident indeed that the oscillatory motion can then no more produce such a velocity, and we know also that, in that case, it will change into a continued motion of rotation. If we exclude this circumstance, the formulæ (1) and (2) will determine generally every particular regarding oscillatory motions. When the amplitudes of the oscillations become so small that we can, in the series (1), neglect all the powers of $\sin.^2 \frac{1}{2}\alpha$, compared with the unity which precedes them, we will have simply

$$T = \pi\sqrt{\frac{l}{g}}.$$

Now, the angle α entering no more into the value of T, it appears that its value will have no influence on it; that is to say, that *for the same pendulum moved in a vacuum, all the oscillations which are performed with amplitudes infinitely small, are of equal durations.*

In actual experiment, the oscillations can never be altogether infinitely small, but we may take care, at least, to confine them within amplitudes so limited that the angle α has a very small value. We have then an approximation perfectly sufficient in limiting the series to the term which contains the square of the sin. $\frac{1}{2}\alpha$. We may then, in the same order of approximation, substitute $\frac{1}{4}\sin.^2\alpha$ for $\sin.^2\frac{1}{2}\alpha$; and the series (1), being thus limited to its two first terms, gives

$$T = \pi\sqrt{\frac{l}{g}}\left\{1 + \frac{1}{16}\sin.^2\alpha\right\},$$

α being always the half amplitude of the oscillation.

We have seen above, that, by supposing the simple pendulum l isochronous with the compound pendulum of the mass m, we have

$$l = \frac{c}{mh},$$

c being the momentum of inertia of the mass m, relatively to the axis of suspension. But if we call c' the momentum of the same mass, relatively to an axis parallel to the preceding, and passing through the centre of gravity G, we find, by mechanics, that the quantities c, c' have between them the following relation :

$$c = mh^2 + c'.$$

This value of c, being substituted in the expression of l, gives evidently

$$l = h + \frac{c'}{mh}.$$

Now, when h is given, this expression only furnishes one value of l; that is to say, a single length for a simple pendulum isochronous with the mass m. But if l be given, then there are two values of h which give the same value to l; and these are deducible from the preceding equation, by taking h in it as the unknown quantity. If we denote these two values of h by h' and h'', it is easy to see that their sum is l, and that thus the first being SG (fig. 1), the second will be PG. If, then, after having placed the axis of suspension in S, we place it in P, that is, in the centre of oscillation itself, preserving it always parallel to its first direction, the oscillations performed round the axis P will be of the same duration as those performed round the axis S, provided always that in both cases the amplitudes of the oscillation, as well as the initial velocities, are equal. This remarkable theorem we owe to Huygens.

It is easy to extend it to one much more general. In all solid bodies, whatever be their figure, we may draw through the centre of gravity three rectangular axes, termed in mechanics *principal axes*, and which possess several properties extremely remarkable. Let the momentum of inertia of the mass m relatively to these axes be denoted by A, B, C. Then, if we consider any axis of suspension of which the distance from the centre of gravity is expressed as above by h, and which forms with the preceding certain angles, X, Y, Z ; it is shown, in mechanics, that the momentum of inertia c'', relative to this axis, can be expressed in the following manner :

$$c'' = mh^2 + A\cos.^2 X + B\cos.^2 Y + C\cos.^2 Z\,;$$

and this value being substituted in l, instead of the letter c, gives

$$l = h + \frac{A\cos.^2 X + B\cos.^2 Y + C\cos.^2 Z}{mh}.$$

If, now, the axis of suspension be given along with the distance h, this expression gives but a single value for l; but if we regard l as given, and constant, then there arises between the angles X, Y, Z, and the distance h, a simple relation, which we can satisfy in an infinity of different ways, so that there result as many different axes of suspension, which are all isochronous with each other. To be sensible of the extensive application of such solutions, let us transform the preceding relation into one with rectilineal co-ordinates. Let x, y, and z, be such co-ordinates directed rectangularly, according to the three principal axes of the mass m, and having their common origin at the centre of gravity of this mass, the axis of suspension relatively to these co-ordinates will have its equations of the form

$$(4.)\quad x = az + \alpha \qquad y = bz + \beta,$$

a, b, α, β, being four constant indeterminate quantities, depending on their position in space. We have, besides, by the well-known theorems of analytical geometry,

$$\cos. X = \frac{a}{\sqrt{1 + a^2 + b^2}},\ \cos. Y = \frac{b}{\sqrt{1 + a^2 + b^2}},$$

$$\cos. Z = \frac{1}{\sqrt{1 + a^2 + b^2}},\ \text{and, lastly,}\ h = \frac{\sqrt{\alpha^2 + \beta^2}}{\sqrt{1 + a^2 + b^2}}.$$

By substituting these values in the general expression of l, it becomes

$$(5.)\quad l = \frac{\sqrt{\alpha^2 + \beta^2}}{\sqrt{1 + a^2 + b^2}} + \frac{Aa^2 + Bb^2 + C}{m\sqrt{\alpha^2 + \beta^2}\sqrt{1 + a^2 + b^2}}.$$

By supposing l constant, this relation, combined with the equation (4), will characterize the isochronous axes : but as this combination only furnishes three equations, while there are four constant indeterminate quantities a, b, α, β, in the position of the axis, it hence appears that we may still assume at pleasure an additional condition among the quantities themselves, after which, by eliminating them, we shall have, in *xyz*, the equation of a surface on which will be found the isochronous axes fitted to satisfy the condition prescribed.

Having thus made known the laws of oscillatory motion in a vacuum and round an axis altogether free from friction, let us now consider them in a feebly resisting medium like air, and supposing a slight degree of friction round the axis, such as is invariably the case in the experiments.

In the first place, whatever be the nature of the physical process by which the two causes operate, their definite effect will always be to retard the pendulum, according to a certain function of the velocity. But whatever be the form of this function, provided it be such as to become nothing when the velocity is nothing, which is an essential condition of the kind of obstacles it is designed to express, we may always assign a simple pendulum which, moving with the same laws of friction and resistance, will be exactly isochronous with the compound pendulum we are considering; and, what is very remarkable, the length of this simple pendulum is exactly the same as it would be if the oscillations were performed in a vacuum, and consequently the same as that of which we have given the expression above. Thus the centre of oscillation of solid bodies, such as we have defined it, has in each of them a situation independent of the medium in which they move, and of the resistances of every kind which their motions may suffer. This important proposition was first demonstrated by Clairault.

Now, for the simple pendulum, as well as for the compound one which accompanies it, the resistance of the air and the friction of the axis diminish continually the extent of the arcs in which the successive oscillations are performed; but it happens, from a circumstance well worthy of remark, that when this retarding force is very slight, and acts with continued and equal effect on both sides of the vertical, the durations of the oscillations are not altered on this account. For, although the resistance which the pendulum suffers must retard, no doubt, its fall, and consequently prolong its duration in each half oscillation in descending; yet in each half oscillation in ascending, this same cause accelerates the extinction of the velocity, and rather brings on the instant when this half oscillation is terminated. And whatever be the mathematical law of the motion thus performed, if the amplitudes of the successive oscillations diminish very slowly, which always takes place when the body put into oscillation has a very considerable density relative to that of the air, and if we make it perform vibrations only of very small extent, and round an axis of suspension so worked as to present but a slight degree of friction, then the motion of the pendulum presents a succession of velocities almost exactly similar in each descending half oscillation, and in the ascending half which follows it. The alterations produced in these velocities by the friction and the resistance of the air are then almost equal, so that their effects are almost exactly compensated in the actual observations. Hence it follows that the isochronism of small oscillations, though altered in each particular half oscillation, is still found to subsist in the total oscillations, notwithstanding of the friction of the axis and the resistance of the air, provided always that these two forces are rendered so feeble as to have but a very gradual influence on the motion. This is at least proved by experiment; for, when a compound pendulum of any form whatever oscillates in the air round a suspension, so free that the decrease of its vibrations goes on with great slowness, if we observe the amplitudes of these vibrations at intervals so near each other that their absolute diminution is inconsiderable, and apply to the number of oscillations performed during this interval the reduction of amplitude calculated according to the mean value of the arcs thus observed; the number of oscillations corrected and reduced in this manner to the case of amplitudes infinitely small, is also found invariably the same for the same pendulum, at least with all the degree of exactness admitted by physical experiments; which shows that the correction of the amplitude is the only one which the oscillations require in order to reduce the motion of the pendulum to a uniformity quite mathematical. This spontaneous compensation, which is produced in the effects of the resistance of the air on the two descending and ascending half oscillations, had first been remarked and pointed out by Newton in his *Principia*, lib. ii. prop. xxvii. theor. xxii. coroll. 2. He even gives a rigorous demonstration of it in prop. xxvi. and xxvii. for the case of a resistance proportional to the two first powers of the velocity —the motion being then in the cycloid. M. Poisson has given the analogous demonstration for a circular motion in the seventh volume of the *Journal de l'Ecole Polytechnique*. These demonstrations, however, only apply to that part of the resistance which arises from the direct impulse with which the moving body strikes the aërial particles, supposing these particles quite removed after the stroke, and consequently without regard to the peculiar agitation which their displacement produces in the medium itself. But, as Newton remarks in the corollary above cited, the descending half oscillation, which is performed with a motion continually accelerated, must, on this account, excite a resistance in a slight degree stronger than the half oscillation ascending, which goes on with a motion continually retarded; because, in this second case, the aërial particles struck by the pendulum may fly from it, and withdraw themselves from its action more easily than in the former. This diminution of the resistance in the second half of the oscillation must cause it to last a little longer than it would have done without this circumstance, and thus the time of the whole oscillation must be a little augmented. Fortunately this cause, it appears, becomes insensible in the most important experiments to which the pendulum is applied; for in these the observations are never made but with very small amplitudes, which produce very small velocities, and these cannot excite any sensible resistance except by the direct impulse communicated to the ambient medium.

But, independently of its resistance, the air, by its mere presence, floating round the oscillating body, produces on the motion another effect, which may be called *statical*, and which must be attended to, in order to compare the observations made in different states of this fluid. As a gravitating medium, in fact, it deprives the oscillating body of a part of its weight equal to that of the volume of air which the body displaces, so that the latter, in reality, only gravitates in consequence of the difference between these two quantities. To calculate the resulting effect on the oscillations, call P the absolute weight of the body in vacuo, Δ its density, compared with that of the air in the circumstances under which we are operating. The weights of bodies of equal volume being proportional to their densities, the weight of the air displaced by the body will be $P \cdot \frac{1}{\Delta}$; thus the apparent weight of this same body, during its oscillations, will be $P - \frac{P}{\Delta}$, so that it will be to its absolute weight as $1 - \frac{1}{\Delta}$ to 1. The effect, then, will be the same as if the absolute weight P were acted on, not by the actual gravity itself, but by a force diminished in this ratio. We have only, therefore, to reduce the elements of this correction to terms that we can compare together. For this purpose, suppose that at the temperature of freezing, and under an atmospheric pressure measured by a column of mercury of 0·76 metre in height, D represents the density of the substance of the pendulum, that of the air being taken as unity. If we denote the cubic dilatation of this substance for a change of temperature equal to a centesimal degree, by c, its density at t degrees will become very nearly $D\,(1-c\,t)$; and if p is the atmospheric pressure at this temperature, the corresponding density of the air, according to the known law of the dilatation of this fluid, will be

$$\frac{p}{0^{m}\cdot 76(1\cdot + t\cdot 0\cdot 00375)}.$$

Then denoting the absolute intensity of gravity, as it is exerted on the body in vacuo, by g, and the apparent force with which it really moves the body in the air by g', we shall have

$$g' = g\left\{1 - \frac{p}{0^{m}\cdot 76(1+t\cdot 0\cdot 00375)(1-c\,t)D}\right\}.$$

To illustrate the use of this correction, let l' represent the length of a simple pendulum, which performs its oscillations in the time T', under the influence of the apparent gravity g', and with the amplitude $2\alpha'$, we shall have

$$T' = \pi\sqrt{\frac{l'}{g'}}\left\{1 + (\tfrac{1}{2})^2 \sin.^2 \tfrac{1}{2}\alpha' +, \&c.\right\}.$$

In the same manner, if we call l the length of a simple pendulum, which makes its oscillations in the time T, under the influence of gravity g, and with the amplitude 2α, we shall have

$$T = \pi\sqrt{\frac{l}{g}}\left\{1 + (\tfrac{1}{2})^2 \sin.^2 \alpha +, \&c.\right\}.$$

If onw we wish the two pendulums to oscillate with equal amplitudes, we have only to make $\alpha = \alpha'$; if we wish, also, to have their times of oscillation equal, we have only further to suppose $T' = T$, then the two preceding expressions being equal to each other, we obtain $\frac{l}{g} = \frac{l'}{g'}$ and $l = l'\frac{g}{g'}$, from which we can calculate l, when we know from observation l' and $\frac{g}{g'}$.

As the density of the solid mass of the pendulum is usually very great, compared with that of the air, D is a very considerable number, so that this correction is always very small. Bouguer appears to have been the first philosopher who made use of it, as appears by his work on the figure of the earth. But before him Newton was well aware of the necessity of paying attention to it, as we may conclude even from the enunciation which he gives to the propositions regarding the resistance of the air above alluded to. For he there compares the motion of the pendulum, affected by this resistance, to that which would take place in *a medium of the same specific gravity, and which would present no resistance.*

Having thus explained in general the mathematical laws of the motion of the pendulum, whether in the air or in vacuo, we shall now describe the principal applications which have been made of them in physical science. These are, 1*st*, the measurement of time; 2*d*, the estimating of the resistance of fluid media; 3*d*, the comparison of the intensities of gravity on different parts of the surface of the terrestrial spheroid, from which certain positive conclusions have been drawn regarding the figure of a spheroid, as well as the arrangement and the density of the strata of which it is formed.

The first idea of employing the pendulum as a measure of time is due to Galileo; and it occurred to him when he was observing the apparent isochronism of the small oscillations of suspended bodies. But the variation in the length of these oscillations, in proportion as the resistance of the air diminishes their amplitude; the necessity of frequently renewing, by a new impulse, the motion which this resistance was destroying; and, lastly, the tedious necessity of following, and counting directly, the oscillations, one by one, during the whole interval that is to be measured; these proved serious obstacles to a practical and certain use of the instrument. Huygens had the merit of surmounting all these difficulties, by employing the pendulum in clocks to regulate the motions of a system of wheels, acted on by a constant power which tends continually to make them revolve; the pendulum determining the rate of their gradual rotation, by acting on them at equidistant intervals. The pendulum carries at its upper extremity a piece in the form of an anchor, which is termed the escapement, and of which the two ends, carried successively from right to left, and from left to right, by the oscillatory motion, are alternately engaged and disengaged with the teeth of a principal wheel, whose rotation they thus serve to check, and which, in its turn, serves as a similar alternate check to the other wheels. These now turn more or less slowly, according to the relation of the number of their teeth to that of the principal wheel. By applying, then, to their axes one or more indices, which turn on a dial-plate divided on the outside, we obtain by their indications so many unities of different kinds, the amount of which shows the number of oscillations that have been made. These unities of time are *hours, minutes,* and *seconds.* Great care is taken in the construction as well as in the application of the wheels, so that their motion may be as easy as possible, and that they may always obey, with equal facility, the intermitting impressions of the pendulum. The body of the pendulum itself is constructed with particular precautions. It is formed of a rod, or system of rods, of metal, terminated below by a mass also of metal, and very heavy; generally of a lenticular form, which, as the edge lies in the direction of the plane of oscillation, possesses the advantage of diminishing the effect of the air's resistance. Besides this, as the dilatations and contractions of the metal, by the changes of temperature, would lengthen or contract the pendulum, and thus cause it to alter the duration of its oscillations, the stalk of the pendulum is composed of a number of slips of different metals, which are so combined that the centre of oscillation of these slips and of the lenticular weight remains constantly at the same height.

Such is, in general, the mode of applying the pendulum to clocks, which we owe to Huygens, and which, by the exactness it has introduced in the measurement of time, is one of the finest and most valuable presents which the sciences have ever received from the hands of genius.

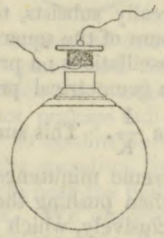
The second application of the pendulum, namely, its use in determining the resistance of fluid media, we owe to Newton, who has explained it with much detail in the sixth section of the first book of the *Principia.* The intensity, and the law of the resistance, are estimated from the progressive diminution of the amplitudes, determined by observation. We may see in that part of the work above referred to, the profound nature of the theory on which this deduction is founded, as well as the experiments themselves to which Newton applies it. The pendulums which Newton made use of were, in general, spheres of wood, or of metal suspended by threads. Besides the law, also, of resistances, several important points in physics depend on this sort of observation. Newton, for example, made use of it to establish the fact, that the action of terrestrial gravity upon all bodies is proportional to their mass; and also to inquire if these bodies, when in motion, suffer any sensible resistance by the presence within them of subtile media, which have been supposed to spread throughout the whole universe.

Lastly, it now remains to consider the use of the pendulum in measuring the intensity of gravity on different parts of the terrestrial spheroid; and we have kept this application for the last, on account of the delicate nature of the experiments which it requires, and which are now really performed. It would be of no use to enumerate here all the methods which have been successively employed, and successively abandoned as experiments of greater exactness came to be required. Even the results of these first attempts, though they may have been at the time very useful, cannot now be any more employed, so much do the limits of the errors which they admitted of exceed those which are allowed by our actual processes. These can be reduced to three principal methods; two of them give the absolute measure of the pendulum; the one is due to Borda, the other to Captain H. Kater; the third gives merely the relations of the lengths of pendulums in different places, and deduces these by comparing the number of oscillations performed in the same interval of time by the same compound pendulum, supposed to be of an invariable form, and which is carried successively to the different places of observation.

I.—BORDA'S METHOD.

The method used by Borda was originally described in a memoir inserted in the third volume of the work which Delambre has published under the name of *Base du Système Metrique Decimal.* The same memoir includes a detailed account of a very great number of experiments performed in this manner by Messrs Borda and Cassini, to determine the length of the seconds pendulum at the observatory at Paris. The method of Borda has since been simplified by the French astronomers, so that, without losing any of its original exactness, it has been rendered more easy of execution in travelling, and in places where the observer can only reckon upon the resources he carries with him. Under this new form this method has been employed on a great number of points of the terrestrial arc, comprehended between the Pithiuse Islands and the Shetland Islands. The description of these modifications, and of the results thus obtained, will be found in a volume which forms a sequel to that of Delambre, and which has been published by Biot and Arago. It is from thence that we shall take our general account of this method, the description of which will serve also for the explanation of the others, these having many points in common with it.

Fig. 3.



The fundamental principle of this method consists in employing for a pendulum a system of bodies which approaches the nearest possible in its properties to the simple pendulum, and which we can reduce to this ideal case by corrections equally simple to calculate, and exact in their application. The pendulum is formed by a ball of platina, suspended to a metal wire (fig. 3). The under extremity of the wire is screwed into the bottom of a spherical cap of copper, of the same radius as the ball, and which being applied on its surface with a little tallow, adheres to it in consequence of the pressure of the atmosphere, and of the perfect contact resulting from its sphericity. The other end of the wire is attached to a suspended knife (fig. 4), which oscillates on a plane of agate (fig. 5), furnished with adjusting screws, by which it can be brought perfectly horizontal; a circumstance which is ascertained by placing on this plane a glass spirit-level without its frame. The mass of the knife is previously adjusted, so that its oscillations may be very nearly isochronous with those of the clock, by which the whole pendulum must be regulated. This is done by the motion of a small ring of metal A, which screws round a metal rod T T fixed to the knife, and which, by screwing and unscrewing, approaches to or recedes from the plane of suspension, giving to the momentum of inertia of its mass a greater or less influence on the motion of the system of the knife and its rod. When the isochronism of the oscillations of the knife and of the clock is as perfect as can be obtained by this method, we suspend from the knife the wire and ball, giving to the wire such a length that the oscillations of the whole system may differ but little from those of the clock, consequently from those of the knife itself. It can then be shown, as well by calculation as by experiment, that the mass of the knife exerts no sensible influence on the length of the pendulum, which arises from its centre of gravity being then excessively near the plane of suspension. The whole system of the knife, the ball, and the wire, has only now to exert an effort infinitely small to complete the exact regulation of the oscillations of the knife, and to make them agree with those of the whole system.

Fig. 4.

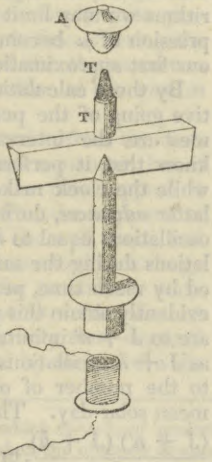


Fig. 5.

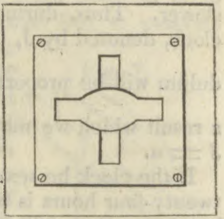


The pendulum is enclosed, with the clock, in a glass case, where it is exempt from the agitation of the air. Behind the wire, at a very small distance, is fixed horizontally a scale of equal parts, which serves to measure the amplitudes of the oscillations. Two sensible thermometers, carefully adjusted, are fixed near the wire, the one at the height of the plane of suspension, the other at the height of the ball, in order to indicate, at every instant, the temperature of the air around the wire. But as the wire, on account of the smallness of its mass, receives the impressions of temperature much more rapidly than the most sensible thermometer, the experiment is made in a room so large and sheltered, that the temperature of the air in it may change very slowly. The state of the thermometers is observed through the glasses of the case without ever opening it during the period of the oscillations.

Every thing being thus disposed, we place, at the distance of seven or eight metres, a telescope fixed horizontally, and the eye-glass of which has a wire fixed vertically before it. We direct this wire upon that of the pendulum when in a state of rest, and we then place in the same direction, on the ball of the clock, also at rest, a small circle of paper to serve for an index. These preparations being made, the clock is set to oscillate, and is no more stopped. When its rate of going has become very steady, we cause the pendulum also to oscillate, and shutting the door of the glass case, we proceed to observe it from without with the telescope. If it should move exactly at the same rate with the clock, it would always be found in the same position in relation to the index in all its consecutive oscillations. But this never happens, and the pendulum goes always quicker or slower than the clock. If it goes quicker, it only coincides for an instant with the index, after which it passes it, recedes from it, returns to it in the opposite direction, passes it anew, and, after having receded from it again, returns to coincide with it a second time, and follows its motion of oscillation for an instant. The telescope which serves to observe these separations and these coincidences magnifies the arc described by the pendulum and by the clock, augments their apparent velocity, and thus enables us to judge of the instants of coincidence with singular precision. Between two consecutive coincidences the pendulum gains or loses two oscillations upon the clock, and a simple proportion determines how much it must gain or lose in twenty-four hours of the clock if it be sexagesimal, or in ten hours if it be decimal. If we suppose N to denote the interval between two coincidences, in clock time, it follows, that while the clock makes N oscillations, the pendulum makes $N \pm 2$; the sign + being employed if the pendulum goes quicker than the clock, and the sign — if it goes slower. Thus, during any number of oscillations of the clock, denoted by J, the number of oscillations of the pendulum will be proportionally $J \left\{ \frac{N \pm 2}{N} \right\}$, or $J \pm \frac{2J}{N}$, a result which we may represent in an abridged form by $J \pm n$.

If the clock be sexagesimal, the number J of its beats in twenty-four hours is 86,400. If it be decimal, this number is equal to 100,000. Both these systems have been employed by the French observers. Whatever may be the one which we adopt, we regulate the length of the wire of suspension in such a manner that the coincidences of the pendulum with the clock may not be very near to each other, which would multiply unnecessarily the trouble of the observer. But neither must they be made too distant, because in that case the pendulum and the clock, detaching themselves too slowly from each other, the precise instants of each coincidence become more difficult to observe. A few trials will soon point out a convenient medium between these extremes. Then the difference in the diurnal rate $\pm \frac{2J}{N}$, or n, between the pendulum and the clock, always forms a very small number of oscillations. But the extent of the arcs described by the pendulum, diminishing always by the effect of the resistance of the air, while the clock, having its motion restored by the action of its weight, preserves always the same amplitude, it hence always happens that the intervals between the successive coincidences of the same pendulum vary with the time, which alters the value of the number n. During this inevitable change, the period when the coincidences are observed with the greatest precision is that where the amplitudes of the oscillations of the pendulum and of the clock are equal to each other; so that if we are obliged, by any consideration, only to observe a small number of coincidences, we must regulate the primitive range of the pendulum, so as to approach as near as possible this condition of equality.

The difference in the rate $\frac{2J}{N}$ or n corresponds with those oscillations of the pendulum which are performed between the coincidences which we compare together, that is to say, with an amplitude of arc varying from 2α at the beginning of the interval to $2\alpha'$ at the end of it. The duration of these oscillations is larger than if the oscillations had been performed with the same pendulum, but with amplitudes infinitely small; and, therefore, to render the results comparable with each other, they must be reduced to this latter case. For this purpose, at the moment of each coincidence, we observe, through the fixed telescope, the point of the horizontal scale at which the wire stops in its excursions on each side of the vertical. This furnishes sufficient data to calculate the angular deviation of the pendulum from the vertical, at the instant of the coincidence, since we know the distance of the scale from the plane of suspension at which the centre of rotation lies. We mark also the state of the interior thermometers, and that of the barometer, at the same instant. If the arcs α and α' are both very small, as it is usual to make them, we may, without sensible error, suppose all the oscillations made with the mean amplitude $\alpha + \alpha'$. Then, after what has been shown above, each of them, expressed in oscillations infinitely small, will be equal to $1 + \frac{1}{16} \sin.^2 (\alpha + \alpha')$, which we may express in an abridged form by $1 + \mu$, and consequently the $J + n$ oscillations of the pendulum supposed to be made in this arc will be equal to a number of oscillations infinitely small, expressed by

$$(J + n)(1 + \mu), \text{ or } J + n + \mu (J + n),$$

a result which we may represent in an abridged form by $J + n'$; the number n', according to what has been above established, never being any way considerable.

If the arcs 2α, $2\alpha'$ differ more than in a slight degree from each other, as, for example, when the interval between the coincidences which we compare is large enough for permitting the resistance of the air to have a considerable effect in modifying the first of these arcs, it will then be no more sufficiently exact to suppose all the oscillations made with the mean amplitude $\alpha + \alpha'$. But this inconvenience may be remedied, by observing experimentally the law of the gradual decrease of the amplitudes. This law is in geometrical progression when the number of oscillations increases in arithmetical progression; that is, if we begin with the instant when the half amplitude was α, and represent by α_n the amplitude which takes place after n oscillations, we find $\alpha_n = \frac{\alpha}{K^n}$, or because α and α_n are supposed very small, $\sin. \alpha_n = \frac{\sin. \alpha}{K^n}$; K being a co-efficient, which, in the same state of the air, is constant for the same pendulum, and depends on its length, its shape, and its other physical qualities. This law, first remarked by Borda, and since confirmed by the other French observers, is a necessary consequence of the smallness of the amplitudes, and of the feebleness of the resistance, which alters each amplitude in succession, proportionally to its extent. But however this may be, it is enough that it really subsists, to enable us to calculate by it the exact sum of the squares of the half amplitudes in the successive oscillations; a problem which is reduced to the summing of a geometrical progression of n terms, of which the ratio is $\frac{1}{K}$. This sum is simplified when we consider the extreme minuteness of the arcs which we compare, and by then pushing the approximation to their second power inclusively, which is the limit of the correction necessary for each individual amplitude. We thus find

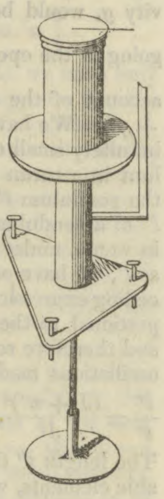
$$\mu = \frac{\sin. (\alpha + \alpha') \sin. (\alpha - \alpha')}{32 \, M \left\{ \log. \sin. \alpha - \log. \sin. \alpha' \right\}};$$

M being the modulus of the tables of common logarithms, or 2·30258509. If we suppose the arcs α and α' so small, that in the development of their series and of their logarithms we may limit ourselves to their first power, this expression of μ becomes what we have already obtained by our first approximation.

By these calculations we ascertain the rate of the relative going of the pendulum on the clock, which serves to measure the intervals between the coincidences. We know that it performs $J + n'$ infinitely small oscillations, while the clock makes J of them. Suppose now that the latter *advances*, during the mean solar day, a number of oscillations equal to h, that is, that it performs $J + h$ oscillations during the same time that a clock, exactly regulated by mean time, performs the exact number J, we shall evidently obtain this proportion; J oscillations of the clock are to $J + n'$ infinitely small oscillations of the pendulum, as $J + h$ oscillations of the clock, or a mean solar day, are to the number of oscillations of the pendulum during a mean solar day. The latter number is thus found equal to $\frac{(J + n')(J + h)}{J}$, or $J + n' + h + \frac{hn'}{J}$, the quantity which, for simplicity, we shall represent by $J + n''$. With the apparatus so disposed as we have described, if the clock is not very far from mean time, so that h denotes a small number of oscillations, the correction expressed by the last term, the only one which demands a calculation, will be of an extreme minuteness, and easily obtained with great precision.

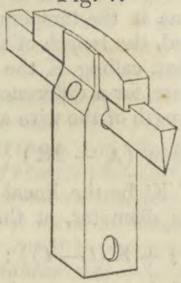
It now remains to measure the length of the pendulum from the plane of suspension to the bottom of the ball of platina. For this purpose we place beforehand, under this ball, a small plate of metal, well polished, perfectly horizontal, and which can be made to sink or rise vertically by means of a screw, of which the threads being very fine, permit the smallest motion. When the coincidences are finished, we open the glass case, and we raise gently this plane until it comes in contact with the ball of platinum. We must be equally careful to avoid raising it too much, which would raise the ball, and make the pendulum too short, or not raising it so high as the contact, which would give a pendulum too long; but if we take for an index the disappearance of a thread of light between the plane and the ball, at their common point of contact, we may then succeed, by a little skill, in fixing this contact with the utmost degree of rigour. This, however, is never done at the first attempt, for the entry of the observer into the glass case, however short, always elevates in a slight degree the temperature of the air contained in it, and consequently that of the wire, which acquires this temperature in the same instant, from whence arises a small increase of its length, which we ought to be aware of. On this account, instead of establishing a perfect contact between the plane and the ball, in that accidental state of the wire which the interior thermometers, less sensible than it, do not perhaps indicate with sufficient exactness, it is better to confine ourselves at first to the mere preparing for the operation, by making the little plane approach extremely near the ball, without, at this time, actually touching it. We observe now the point where the index of the screw that moves the ball stops, and then coming out of the glass case, we shut it until the temperature within, and the thermometers which measure it, have had time to return to a state of rest. We then open the case anew, and finish in an instant the operation of contact, which is easily done, as we have only to give to the plane of contact a very slight degree of motion, and such as we are previously quite prepared for. At this moment, or rather before entering the glass case, we mark the temperature of the thermometers within, and consider this as the temperature of the wire at the instant of contact.

Fig. 6.



The distance of the plane of suspension from the bottom of the ball is now fixed, and in such a manner that it is henceforth invariable, or at least we may suppose it such during a long interval of time. For, the supports of the plane of suspension being fixed in the wall itself, and those of the plane of contact being cemented to a large stone resting on this wall, or sunk into the ground, the accidental variations of temperature cannot alter the distance which separates them, excepting in a very slow degree.[1] It remains then to measure this interval by means of a divided rod of metal; but to determine the length of such a rule, its extremities must be quite free; and how can we, in that case, apply its summit exactly on a level with the plane of suspension? Borda has very happily resolved this difficulty, by adapting to one of the extremities of the rule a knife of suspension, which is fixed to it, so as to touch it on its edge. Suppose we wish first to measure the length of the rule, we take off the knife, and apply the rule itself to the apparatus intended for that object. If we wish then to measure the length of the pendulum, we replace the knife, and suspend the rule, thus armed, on the plane of suspension, in place of the pendulum itself. In our experiments, the knife is adapted to the rule by means of a metal case; the rule is inserted into this case until it touches the knife, when it is fixed in this position by means of a strong pinching screw, denoted by V, and which is screwed by an iron key. It only remains to alter the length of this rule in such a manner as to render it exactly equal to the actual distance which is found between the bottom of the ball and the plane of suspension. For this purpose, in the experiments of Borda, the rule carried, on its under part, a divided tongue, having a free motion. When the observations of the coincidences were finished, the pendulum was removed, and for it was substituted this rule, of which the tongue was let down until it fell upon the little plane which had touched the ball of the pendulum. Then, by reading, with a magnifying glass, the divisions of the tongue, it is easy to know the distance between the bottom of the ball and the axis of suspension.

Fig. 7.



In Borda's experiments, the pendulum was twelve feet long. A rule of such a length could not have been carried in travelling, or even in stations of difficult access, without the risk of serious errors, resulting from the bending which it must have received. On this account the French observers, who were intrusted with such experiments, thought it necessary to modify in this point the apparatus of Borda, and they confined themselves to pendulums much shorter; as are those which swing mean sexagesimal or mean decimal seconds. This enabled them to make use of rules much shorter, more portable, and which they could also make larger and more solid without increasing too much their weight; but then it became indispensable to introduce a still greater degree of precision than before into the determination of the length of the rules; into that of the divisions traced upon the tongues which were fixed to them; and, lastly, into the measurement of the variable parts of these tongues, which were used in each experiment, in order to adapt them to the different lengths of the pendulum which they were intended to measure. All these elements were obtained with unexpected exactness, by employing for their determination the apparatus already used with such success for the comparison of metrical scales, under the name of *comparateur*. All the details of this application may be seen in the work of Biot and Arago, above referred to.

By means of the operations above described, we find the total length of the pendulum, from the plane of suspension to the bottom of the ball of platina; such at least as it is at the instant of contact of the latter with the little plane. But this length may not be, and is not in general, the same which the pendulum has when it began to oscillate; because the temperature, which modifies almost instantaneously the length of the wire, cannot have been the same at the time of the contact of the plane, and during the observation of the coincidences. But it is to this state that we must evidently reduce the length that we have attained. For this purpose, let it be denoted by Λ, and suppose t' the temperature of the wire in degrees of the thermometer at the instant of contact, t being its mean value during the coincidences; then if R' represent the radius of the ball of platina at the temperature of t' when the contact was produced, the length of the wire at that instant was $\Lambda - 2R'$; so that, calling K the lineal dilatation of the matter of the wire, for a difference of one degree in the temperature, the length of the wire at the time of the oscillations must have been $(\Lambda - 2R')\left\{1 + K(t - t').\right\}$ In the same manner, if K' be the lineal dilatation of the substance of the ball, its diameter, at the time of the oscillations, will be $2R'\left\{1 + K'(t - t')\right\}$; and adding this quantity to the length of the wire, we obtain $\Lambda + \Lambda K(t - t') + 2R'(K' - K)(t - t')$ for the distance of the plane of suspension from the bottom of the platina ball during the actual time of the oscillations. By deducting from this length the radius of the ball, such as it was at the same instant, that is, $R'\left\{1 + K'(t - t')\right\}$, we shall have the distance of the centre of the ball from the plane of suspension, a distance which we shall call h. This being determined, if the wire which sustains the ball, and the cap which fits upon its surface, were both without weight, or if their weight could be altogether neglected in comparison with that of the ball, the length l of the simple pendulum isochronous with the compound one thus formed would be obtained by the above formula, and would be $l = h + \frac{c'}{mh}$, m being the mass of the ball, and c' its momentum of inertia relative to an axis drawn through its centre. But calling ϱ the density of the mass of the ball, and R its radius, at the temperature at which the pendulum oscillates, its mass m is equal to $\frac{4}{3}\pi\varrho R^3$, and the value of c' is $\frac{8}{15}\pi\varrho R^5$. Substituting these values, we have $l = h + \frac{2R^2}{5h}$; hence it appears, that it would be easy to calculate l, since R and h are known. But, in truth, the weight of the wire and that of the cap can never be absolutely nothing. They are only very small, relatively to the weight of the ball; so that the preceding value of l is but an approximation, which, to become quite exact, requires a small correction, depending on the relation of these masses. This correction being rather complicated in its expression, we shall not repeat it here, but refer to the memoir of Borda, or the work of Biot and Arago, already mentioned, and represent it by Q; as it is always negative, the length l of the simple pendulum isochronous with the pendulum observed will become $l' = h + \frac{2R^2}{5h} - Q$. Now we have seen, that, in these experiments, the apparent gravity which impels the pendulum is less than the real gravity which operates in vacuo, on account of the statical effect of the ambient medium; but for a simple pendulum of the length l moved by the force of gravity g, the time T of its infinitely small oscillations is expressed by $\pi\sqrt{\frac{l}{g}}$; and if we wish to obtain oscillations of equal duration with different forces of gravity, we must vary the lengths in proportion to these forces, so that the relation $\frac{l}{g}$ may remain constant. Now, after what we have before seen, if we denote by D the density of the substance of the pendulum at the temperature of freezing, and under the atmospheric pressure of $0^m{\cdot}76$, that of the air being 1, if, besides, we denote by c the cubic dilatation of this same substance, the relation of the apparent gravity in air to the gravity in vacuo, under the pressure p, and at the temperature t, will be expressed by $1 - \frac{p}{0^m{\cdot}76\,(1 + t.0{\cdot}00375)(1 - ct)\,D}$, which, for simplicity, may be represented by $1 - \gamma$. Then, to obtain the length l'' of the simple pendulum, which, making its oscillations in vacuo under the influence of the gravity g, would be isochronous with the actual pendulum l', going in the open air, we must take $l'' = \frac{l'}{1 - \gamma}$, which, on account of the smallness of γ, may be reduced to $l'' = l + \gamma l'$. We have denoted above by $J + n''$ the number of infinitely small oscillations performed by the actual pendulum in a mean solar day. Such, then, is also the rate of the pendulum l''. If we wish, in fine, to obtain the length l''' of a pendulum which would move exactly to mean time in vacuo, under the influence of the same power of gravity as l'', we have only to consider that, according to the preceding expression of T, the lengths l'' must be directly proportional to the squares of the times of their oscillations, and therefore reciprocally as the squares of the number of oscillations made in equal times. We must take, then, $\frac{l'''}{l''} = \frac{(J + n'')^2}{J^2}$, whence we obtain $l''' = l''\frac{2n''\,l''}{J} + \frac{n''^2 l''}{J^2}$. The length l''' thus obtained is now free from all the variable elements, which depend on particular circumstances of their observations. This constitutes what we should properly call the absolute length of the simple pendulum in the place of observation.

---

[1] Considering the indispensable necessity which there is of preserving rigorously this quantity invariable, it appears to be of extreme importance that the ground may not yield when the observer approaches to complete the measurement. The only means of avoiding, beyond suspicion, this possibility, is to construct round the pendulum a platform, supported on certain points of the ground, at a distance from the stone which carries the little plane with which we effect the contacts of the ball, so that this apparatus may become quite independent of the motions of the observer.

The experimental method which we have described, when it is employed with all due care, gives results which, in the same place, are perfectly comparable with each other. For, with various lengths, such as the sexagesimal pendulum, for example, or the decimal pendulum, the deductions from particular experiments do not differ generally from each other more than in the thousandth parts of a millimetre. To establish, however, completely the theoretical certainty of this method, it is necessary to examine more particularly some of the circumstances which form a part of it.

Our first remark relates to the extensibility of the wire to which the platina ball is suspended. It is clear, that, during the period of each oscillation, the wire is impelled in the direction of its length by two forces of different kinds, and of different intensities; of which the one is the varying traction, acting on it every instant by the weight of the ball decomposed into its direction; and the other is the centrifugal force, which the motion of oscillation generates. It may evidently be a question, whether this double action has not on the oscillations a sensible influence, which, disappearing in the measurement of the length taken when the pendulum is at rest, would alter the result which we have obtained. M. Poisson has submitted this question to calculation in the eighth volume of the *Journal de l'Ecole Polytechnique*, and he has found, first, that the symmetry of the oscillations on each side of the vertical is not altered by the extensibility of the wire; at least if we suppose them to be performed in vacuo, a circumstance which it was easy to anticipate from the symmetry itself of the mode of action of this force. But he has found that their duration is affected with a periodical inequality, in consequence of which the successive oscillations are not isochronous among themselves. When the total extension, however, suffered by the wire is very small, which is generally the case in experiments where the wires are formed of metallic substances, the effect of this inequality neutralizes itself in the mean duration of a great number of oscillations; only this mean period is a little longer than if the wire had been altogether inextensible. Let *l*, for example, be the lineal length which the wire would naturally have if left to the sole attractive action of its particles on each other; and suppose that, by suspending the platina ball at its lower extremity, it lengthens by a small quantity λ. This being the case, if the half amplitude of the oscillation is denoted by α, M. Poisson finds that, limiting the results to the square of α, the mean duration T of the whole oscillations will be

$$T = \pi\sqrt{\frac{l}{g}}\left\{1 + \frac{1}{16}\left(1 + \frac{11\lambda}{l}\right)\sin.^2\alpha\right\}.$$

If we wish to suppose the wire inextensible, we have only to make λ equal to nothing, and it hence appears that the extensibility only modifies the correction of amplitude, already in itself so small, and alters it by a quantity which, from the small extensibility of the metals, cannot in general produce any effect that could be detected by observation.

A second circumstance, which deserves equally to be examined, is the probable influence of the motion of rotation of the platina ball round the direction of the wire, and any twisting which the wire may suffer during the oscillations. M. Poisson has examined, by a calculation in the *Connoissance des Tems* for 1815, the effect of such a motion; and he has found that, in the ordinary disposition of the pendulum of Borda, it is rendered in a manner insensible by this circumstance, that the momentum of inertia of the ball, and of the whole pendulum, relatively to an axis drawn through the direction of the wire, is a very small quantity. Let R be the radius of the platina ball, *h* the distance of its centre from the axis of suspension, α the angle which the rotation of the ball makes each of the points of its surface describe during the period of an oscillation, this angle being measured in a circle of a radius equal to 1, T the time of an infinitely small oscillation of the same pendulum, in the case when the rotation is nothing; M. Poisson finds that the real duration of the oscillations will be $T\left\{1 - \frac{\alpha^2 R^4}{50h^4\pi^2}\right\}$, π being always, as before, the circumference to the diameter, which is unit, or, what is the same thing, the semi-circumference, of which the radius is 1. In regard to the effect of the torsion communicated to the wire by the rotation of the ball, M. Poisson proves that it can have no influence on the duration of the oscillations. In the shortest lengths of pendulum which have been observed by the above process, R was less than $0^{m}{\cdot}02$, and *l* nearly equal to $0^{m}{\cdot}74$. Adopting these numbers, and supposing, besides, that the ball describes two whole circumferences for each oscillation, which would be a very rapid motion of rotation, we shall then have $\frac{R}{h} = \frac{1}{37}$, $\frac{\alpha}{\pi} = 4$, and consequently $\frac{\alpha^2 R^4}{50h^4\pi^2} = \frac{1}{5856569}$; whence it appears that the time of the oscillation would be diminished only by a quantity altogether insensible, even on the above suppositions. But it is far from being the case that a rotation so rapid as we have supposed really takes place in the experiments; on the contrary, when we set the pendulum in motion, we take great care to avoid every movement of this kind; we also pay particular attention to let fall the ball without any lateral impulse, so that its oscillation may be performed as exactly as possible in a vertical plane, which we also take care to verify by observation, when the pendulum is in motion. It would be useless to attempt to obtain this condition in a manner more exact; for it is known by the calculation of conical oscillations, that when these take place in an orbit much flattened, their duration is almost exactly the same as if they were quite plain.

The last object to be considered, and of which the discussion is as important as it is delicate, is the influence which the form of the suspending knife may have upon the oscillations of the same pendulum. Comparing, indeed, the motion of the pendulum to that which would take place round an axis of suspension perfectly rectilineal and mathematically straight, we suppose, or at least seem tacitly to suppose, that the edge of the knife forms such an axis, which is physically impossible, since the most perfect art cannot give it any other form than that of a round surface, the breadth of which is sensible to the microscope, and which, even there, appears always like a saw indented with teeth more or less deep. Now, if this surface were a circular cylinder, a simple calculation, which was first made by Euler, shows that the durations of the oscillations will be the same as if they were performed round a rectilineal axis placed *under* the surface of the cylinder, and at a distance equal to the radius of its curvature; and in the case of very small oscillations, this result may be extended to a knife of any form, if we take for its curvature that of its osculating circle. Hence it follows, that in order to have the true length of the simple pendulum in this circumstance, we must subtract the radius of this circle from the length calculated on the hypothesis of a rectilineal axis, according to the oscillations observed. But such a correction would throw great uncertainty upon the results; for the osculatory curvature of the knife cannot be measured, or even appreciated, by any process, and it must vary considerably, either by the difference of workmanship in different knives, or by the inevitable wearing which the edge of the knife undergoes when the weight suspended from the wire presses it against the plane of suspension. Fortunately, the extent, and the variableness itself, of the effects which this cause should produce, serve to prove that it has no action whatever in experiments; for, in the first place, by loading successively the head of the same knife with several weights very different among themselves, in order to observe if these different systems, previously according with the same clock, would have an influence on the length of the pendulum, Borda has found that this influence was absolutely insensible, although the curvature of the edge, to which he did not pay attention, was then undergoing very different modifications under the unequal compressions to which they were subject. Secondly, the length of the simple pendulum, beating seconds at the Observatory of Paris, which Borda had deduced from a pendulum of twelve feet long, has since been found as exactly the same as the difficulties of the operation would permit, by employing, with the same knife and the same ball, wires four times shorter, which gave a much greater influence to the alterations of length which the curvature of the knife could produce. Lastly, by observing successively, at the same place, with the same ball, and the same length of wire, but with knives whose edges presented an extreme diversity, from the highest possible finish to the greatest coarseness in the execution, M. Biot has obtained, at Leith Fort, in Scotland, such lengths for the simple pendulum, between which no sensible difference could be observed, although no correction whatever was made for the curvature of the knife. These proofs of different kinds, but all agreeing in their consequences, seem to show evidently that in the process of Borda the shape of the edge of the knife has no sensible influence on the results, and that it is unnecessary, therefore, to pay any attention to it; and yet, as the theory of oscillations round cylindrical axes cannot be questioned, we must either conclude that in this circumstance the oscillation is really not performed on a cylinder of sensible dimensions, but upon the ideal axis of insensible dimensions, formed by the asperities which still exist in the grain of metal of which the knife is composed; or that the agreement previously established between the proper motion of the knife and the total motion of the pendulum, compensates physically the effect which the curvature of the knife would have upon the oscillations, if it consisted really of a simple cylinder without mass attached to the wire.

II.—METHOD OF KATER.

The method employed by Captain Kater to measure the length of the pendulum is founded upon this theorem of Huygens, that whatever be the form of the oscillating body, the centre of oscillation and the centre of suspension are reciprocals to each other, a theorem of which we have already given the demonstration. To realise this disposition, Mr Kater chose a body of such a form that it was easy to determine by calculation the approximate position of its centre of oscillation for a given position of the axis of suspension. These two points being thus known, he fixes there immoveably two knives parallel to each other. In the space which separates them he then adapts to the body a moveable weight, and having first placed it at random, he makes the system oscillate successively upon the one knife and upon the other. If, as it almost always happens in the first trial, the oscillations performed in the two cases are of unequal duration, he moves the intermediate weight, so as to bring them nearer to an equality; then, comparing these anew by observation, he finds necessarily a less disparity between them, which he again reduces, until at last, after a few trials, the duration of the oscillations performed round the two axes become exactly equal. The justness as well as the rapidity of these reductions are favoured by the form which Mr Kater has chosen for his oscillating body. This form is a simple rectilineal bar of brass, towards the two extremities of which are placed two known weights; the one of which is immoveably fixed, and the other, being moveable, but at the same time capable of being fixed in a similar manner, serves, first, by its motion, to establish between the two knives, not exactly, but approximately, that reciprocity between the oscillations to which it is desired to bring up the system. This reciprocity is then rendered rigorously exact, by the much more delicate motion of a third smaller weight placed between the knives, in that part of the rod where we know, by calculation, the effect of its displacement will have the least sensible influence upon the oscillations, which is found to be towards the middle of the rod, in the division of the weights adopted by Mr Kater. A divided scale, engraved upon the bar of the pendulum itself, serves to measure the displacement of this latter moveable weight. In the experiments of Mr Kater, this scale was divided into twelfths of an inch, and a displacement of twelve parts produced a difference of about four seconds in the diurnal rate of the system, reckoning sexagesimally; whence we may be able to appreciate the extreme delicateness of this mode of regulation. The bar, with its weights, is represented in fig. 1, Plate CCCCIII. Fig. 2 shows its disposition during the observations.

It is then, as appears, placed before a clock, with which it is compared, by means of a fixed telescope, after the method of coincidences of Borda. But the mode of experiment employed by Kater, requiring the oscillations round the two axes to be observed in a state of rigorous equality, it becomes necessary to avoid, in their comparison, every change of temperature, and thus it is necessary to make the results independent of the variations of this kind which inevitably arise in the atmosphere. That could only be obtained by rendering the series of coincidences very short, and multiplying the successive inversions of the apparatus. But then, to obtain the same exactness, it is necessary to fix the coincidences with much greater precision than in the method of Borda, where the little influence which they have is one of the principal advantages. Mr Kater has attained this object, by fixing upon the lentil of his clock a white disc, traced upon a black ground, and of such a size that it is exactly covered, and no more, by the interposition of the bar of the pendulum, when this is at rest in the situation of the vertical. This same occultation, being then observed during the motion of the clock and of the pendulum, serves to fix the instant of the coincidence; and Mr Kater finds, that in this manner there cannot be any error greater than a second on the instant to which each coincidence belongs.

The rest of the details of the observation are the same as in Borda's process. The amplitude of the arc of oscillation is observed at each coincidence, as well as the state of the barometer and thermometer; and these are employed in the same manner to reduce the oscillations to what they would have been if they had taken place in vacuo, and with amplitudes infinitely small, at the observed mean temperature of the oscillating body.

It still remains to obtain the length of the simple pendulum corresponding to this rate of going. After an equality has been obtained in the oscillations round the two knives, this length is equal to the distance between the edges of the knives at the moment of the oscillation of the pendulum, at least if we consider these edges as lineal axes. It would be evidently impossible to observe the distance in question during the actual motion of the pendulum; but this defect may be supplied by determining it first for some known temperature, and reducing it by calculation to the value which it ought to have during the coincidences, according to the temperature at the time these took place, and the dilatation of the substance of the pendulum, which is also known. It is thus that Mr Kater operated, and he has obtained the true distance between the knives, in comparing it by a microscopic process, with the metal rule which he employed as a standard of measure. In order that this operation may be put in practice, the two edges of the knives must be very exactly parallel. Mr Kater accordingly disposed them in this manner before the experiments, employing the measure itself of their distance to determine and to prove the accuracy of their position, to which they were gradually brought by means of adjusting screws, which allowed each knife to move by very small displacements. He also took advantage of this method to render their direction quite perpendicular to the length of the bar. Lastly, as the distance between the knives, which we are seeking to determine, is that which took place when the pendulum was in a vertical situation, Mr Kater, during the measurement, applied to the bar, now horizontal, a force of longitudinal traction equal to what it exerted on itself by its own weight, and in a state of oscillation. In calculating the influence which the curvature of the knives, supposing it to be circular, can have upon the length of the simple pendulum, deduced from the oscillations of a similar apparatus, M. Laplace has found it to be equal to nothing, and that this length was always rigorously equal to the distance between the edges of the knives. This theorem is only true on the supposition that the two edges are of the same curvature; but whatever precaution may be taken to render them identical, even making them together, and with a single piece of steel, it will be impossible to be assured that there may not be found differences, not merely very small, but very considerable, in the radii of curvature of their osculatory circles; since these circles are the result, not of any measured and geometrical operation, but of a work of reducing and polishing necessarily vague and irregular. It would appear then by this, that the results of this method would still be subject to the same uncertainty in theory as the results of the others are; but these uncertainties are dispelled in both cases, by the experimental proofs already described, that, in the process of Borda, the figure of the edge of the knives has no influence upon the length of the simple pendulum, deduced from their oscillations. In short, what completes the proof, that these two methods do not include in themselves any source of inaccuracy, is the surprising and almost ideal coincidence of the results which they afford, notwithstanding the diversity of the two processes. We shall have occasion to give a striking proof of it at the conclusion of the ensuing paragraph.

III.—PENDULUMS OF COMPARISON.

The two methods which we have been explaining make known the *absolute* lengths of the simple pendulum in every place where it is observed. Both of them, therefore, require to be absolutely determined, on the spot, in lineal measures; and this cannot be done with sufficient exactness but by a process of extreme delicacy, the practice of which implies numerous preparations. But when we wish merely to determine the ratios of the lengths of the simple pendulum to each other, for different places on the earth, we may obtain this without any absolute measurement, and by the mere comparison of the oscillations made in these places in equal times by a compound pendulum of any form. To demonstrate this, suppose, first, that the figure of the mass of this pendulum is quite invariable, and that it suffers neither dilatation nor contraction by the changes of temperature; or, what comes to the same thing, suppose the observations are always made during temperatures exactly equal; in this case, according to the formulæ laid down in the beginning of this article, the length l of the simple pendulum isochronous with that compound pendulum, may be expressed by $\frac{c}{mh}$, m being the mass of the oscillating body, h the distance of its centre of gravity from the axis of suspension, and, lastly, c its momentum of inertia; that is to say, the sum of all the elements of its mass, multiplied by the squares of their respective distances from the axis of suspension. This length l, then, will be the same in whatever place we observe it, since its analytical expression depends only on the figure of the oscillating body and the density of its parts, but in no respect on the intensity of the gravitating force which impels it; so that if we take any compound pendulum, of any form whatever, but having its mass and figure constantly the same, and make it oscillate successively in different parts of the earth, it is the same thing as to cause a simple pendulum to oscillate successively in the same places. But, supposing the oscillations performed in vacuo, and with infinitely small amplitudes, or, what is the same thing, supposing them reduced to these conditions by calculation, the durations T', T'' of the oscillations of the same simple pendulum, whose length is l, are connected with the intensities g', g'' of the gravitating force, which impels them by the following relations, $T'^2 = \pi^2 \frac{l}{g'}$, $T''^2 = \pi^2 \frac{l}{g''}$; whence we obtain $\frac{g''}{g'} = \frac{T'^2}{T''^2}$, that is to say, that the intensities of the gravitating forces are reciprocally as the squares of the times of the oscillations; or, what is the same thing, they are directly proportional to the squares of the numbers of oscillations made in equal times. For let N', N'' be these numbers, and T the total time which corresponds with them, then T' will be equal to $\frac{T}{N'}$, and T'' equal to $\frac{T}{N''}$; so that, by substituting their values, the preceding relation will become $\frac{g''}{g'} = \frac{N''^2}{N'^2}$.

By such experiments, then, made with the same compound pendulum, we may be able to determine the relative forces of gravity in the different places of observation. But we may, with equal facility, deduce from them the ratios of the absolute lengths which it would be necessary to give to two simple pendulums in the same places, for making them bear an equal number of oscillations in a given time; for example, to beat the mean second. For let λ', λ'' be these unknown lengths, since the corresponding times of oscillation are each one second, we shall have by our general formulæ $1''^2 = \frac{\pi^2\lambda'}{g'}$, $1''^2 = \frac{\pi^2\lambda''}{g''}$; whence we obtain $\frac{\lambda''}{\lambda'} = \frac{g''}{g'}$; that is, that the lengths required are proportional to the intensities of gravity in the two places. But we have seen that the ratio of the gravitating forces may be deduced from the observations made with the same compound pendulum; and introducing this determination into the preceding expression, we obtain $\frac{\lambda''}{\lambda'} = \frac{N''^2}{N'^2}$. Hence, when we have observed the numbers of infinitely small oscillations made in two different parts of the earth, by the same compound pendulum, of a constant form, the ratio of the squares of these numbers will be equal to the ratio of the lengths of the simple pendulums, which swing seconds in the same places. All these results suppose, as we have seen, that the mass and form of the compound pendulum are rigorously the same at the two stations. To obtain a degree of permanency in the mass, we form the pendulum of metal, cast in one piece, to which we adapt for suspension a knife edge made by a process which insures the firmness of the connection, and we take every precaution possible to prevent any physical or chemical alteration from modifying it during the carriage. But the permanency in its dimensions and figure is much more difficult to be obtained, because the inequalities of temperature in the different places of observation, and the accidental variations of natural heat, even in the same place, tend perpetually to disturb it. It is physically impossible to prevent the effects of these alterations in any other way, than by preserving constantly round the pendulum the same artificial temperature; a method which has been really employed, but which requires very great precautions to render the temperature round the pendulum uniform, and a constant attention to manage the sources of cold and of heat, in order to maintain it at the same fixed degree. It is on this account more simple, and perhaps more accurate, when the thing is possible, to dispose the experiment so as to have only very slow changes of temperature; then to allow the pendulum to partake of these changes, and to correct this effect on its form by calculation, from the observation of the temperature, and the knowledge of the proper dilatation of the substance of which it is composed. This correction is extremely easy; for if we resume the expression $l = \frac{c}{mh}$, which expresses the corresponding length of the simple pendulum, the momentum of inertia c is of the same order as the mass, multiplied by the square of the dimensions of the oscillating body, and the denominator mh is the product of this same mass by a single dimension; whence it is easy to conclude, that if the dimensions should vary in the same proportion in every direction, which really happens in changes of temperature, the quantity $\frac{c}{mh}$ will vary according to this simple proportion. Hence, if we name l the length of this simple pendulum, isochronous with the compound pendulum, when the latter is at the standard temperature t, and denote by l' the analogous length when the temperature is t', representing also by K the lineal dilatation of the mass of the pendulum, for a change of one degree of the temperature, and for a length equal to unity, we shall evidently have $l' = l \; \{1 + K(t' - t)\}$. Suppose now the pendulum l' has made a number N′ of oscillations in a given interval of time, for example, a mean solar day, it will be easy to calculate how many the standard pendulum l would have made in the same time, if it had been acted on by the same force of gravity; for the squares of the numbers of oscillations made in equal times being reciprocally as the lengths of the pendulums which perform them, the square of the number sought will then be

$$\frac{N'^2 l'}{l}, \text{ or } N'^2 \left\{ 1 + K(t' - t) \right\}.$$

Hence we obtain for this number itself $N' \sqrt{1 + K(t' - t)}$; or, reducing the radical into a series, and limiting it to the first power of K, $N' + \frac{1}{2} N' K (t' - t)$. This approximation is always sufficient, because the co-efficient K of the lineal dilatation is always very small in solid bodies, and the difference $t' - t$ of the natural temperatures in the places of observation can never exceed a small number of degrees. Captain Kater, for example, has operated with a similar pendulum, made of brass, the observed lineal dilatation of which was 0·00000982 for one degree of Fahrenheit. In an experiment made in London, this pendulum was found to perform a number of oscillations equal to 86051·32, the temperature being 71°·6. If we wish to reduce this experiment to the standard temperature of 62 degrees, which was adopted by Mr Kater, we shall have $N' = 86051·32$, $K = 0·00000982$, $t' - t = + 9°·6$, whence we obtain, for the correction of the temperature, $\frac{1}{2} N'K (t' - t) = + 4''·04$, that is to say, four oscillations, and four hundred parts, added to the number of oscillations observed. By operating in the same manner in every other case, we can reduce all the observations to the constant temperature once fixed as a standard.

But one of the indispensable elements in this reduction is the actual temperature of the pendulum during the experiments, and some precautions are necessary to obtain it with exactness. For the pendulum being always very large compared with the thermometers, which we can place by the side of it, it partakes much more slowly than them of the variations of temperature, so that it ought always to be a little colder than the thermometers when the temperature of the air is rising, and a little warmer when it descends. It would be impossible to estimate these differences of state; but we can render their effect insensible, by operating in a room, so large and sheltered form the sun that the temperature remains in it nearly constant, or at least suffers such slow variations, that the mass of the pendulum has time to partake of them. For in that case the thermometers will point out the state of this mass in indicating that of the ambient air; or if there remains some difference between both, the effect of this will disappear by compensation in a series of experiments sufficiently repeated.

We have mentioned above, that the corrections relative to the amplitude of the arcs and the density of the air, are made in every place for the compound pendulums, the same as in the experiments with the absolute pendulum. The duration of the oscillations may also be determined in the same manner by the method of coincidences, comparing the experimental pendulum with a clock that is actually regulated by astronomical observations. Thus, in applying this process, and these corrections, we shall obtain the numbers of oscillations which a compound pendulum would have made at the different stations, if it had oscillated in vacuo, and at a temperature always constant. Whence we may then deduce the relation of the intensity of gravity at these stations, or the ratio of the lengths of the simple pendulum, swinging the same fixed number of seconds in a given time.

To give an example of this deduction, we shall relate the following result, obtained in 1818, by Captain Kater, with the same compound pendulum the dilatation of which is stated above. The numbers of oscillations expressed in the last column are reduced by calculation to the case of amplitudes infinitely small, the pendulum in vacuo, and the temperature being the standard of 62° Fahrenheit.

From other experiments previously made by means of the method of inversion, Captain Kater had determined the length of the absolute seconds pendulum at London, precisely at the same place, and in the same room, where he since made his compound pendulum oscillate. This length, expressed in English inches, on Sir George Shuckburgh's scale, was found to be 39·13908 inches. If then we call this length λ, and λ′, λ″ the analogous lengths for the two other stations of Leith and of Unst; also N, N′, N″ the number of oscillations of the portable pendulum in these three stations, we shall have, according to the formulæ above laid down, $\lambda' = \lambda . \frac{N'^2}{N^2}$, $\lambda'' = \lambda . \frac{N''^2}{N^2}$, which will give for the length of the simple pendulum, at the station of Leith, 39·15538 inches, at the station of Unst 39·17141 inches. Now, by comparing, by methods of extreme precision, the scale of Sir George Shuckburgh, with a metre of platina, executed under the directions of the Board of Longitude of France, and verified by a commission of several members of this body, Mr Kater has found that the metre, taken at its own standard temperature, which is that of melting ice, is equal to 39·37079 inches of the scale of Sir George Shuckburgh, taken also at its own standard temperature, which is 62 degrees Fahrenheit. Hence it follows, that any length l expressed in inches of this scale, taken at its standard temperature, is equal in millimetres to $\frac{1000 \cdot l}{39·37079}$. The preceding lengths of the simple pendulum, both at Leith and Unst, being already reduced to this standard state, we may apply to them directly this formula, and deduce in millimetres the following values, which are set down, compared with those of Biot, obtained by the method of Borda, from observations made with great care, the preceding year, in the same stations of Leith and Unst.

Names of the Stations.	Lengths of the Simple Pendulum according to Kater.	Lengths of the Simple Pendulum according to Biot.	Differences of Kater's Measurement.
	m m	*m m*	*m m*
Leith Fort	994·528685	994·524453	+ 0·004232
Unst.........	994·935840	994·943083	— 0·007243

The differences of the results, it will be seen, are excessively minute, for they consist only in some thousandth parts of a millimetre, which is equal to $\frac{39}{1,000,000}$ of an English inch; and they are, besides, affected with contrary signs at Unst and at Leith. We may reasonably conclude, then, that they fall within the limits of that uncertainty to which all physical results are subject; and it may therefore be inferred, that the method of Borda and that of Captain Kater are equally precise, and both give, with exactness, the absolute measure of the pendulum.

In attempting to carry compound pendulums on distant journeys, or when we are obliged to observe them in places where the apparatus cannot be fixed to solid buildings, this must necessarily be modified, so as to be complete in itself. To do this, we may prepare for the pendulum a support of metal, made from a single casting, the feet of which spreading out, can be firmly fixed in the ground, while they allow the pendulum, at the same time, to oscillate at freedom between them. The upper part of this support must consist of a plate having a longitudinal opening in it, to allow the stem and knife of the pendulum to pass through. On this is fixed, with long screws, a polished plate pierced with a similar opening, and which can be set horizontally with a spirit-level before fixing it; and it is on this plane that we place the knife of the pendulum. A divided scale, unconnected with the pendulum, is placed horizontally, immediately under the lower extremity of its stem, which being furnished with a point, indicates, by its excursions upon this scale, the amplitudes of the oscillations. In order, now, to determine the rate of the pendulum's going, it is not always possible to procure the necessary facilities for employing the method of coincidences. In that case, we may substitute for it the comparison of the pendulum with an adjoining clock, or else with a chronometer, counting, as Bouguer did, the whole oscillations which the pendulum performs during a given time, and determining the fractions of oscillations, by observing the part of the amplitude with which the point of the stalk corresponds at the commencement and termination of the interval of the time observed. But in making use of this last process, which is indispensable for fixing the extreme terms of each compared interval, we can dispense with the counting of the oscillations one by one; for it will be sufficient to follow them with a counter, the rate of which is adjusted very nearly to that of the experimental pendulum, and which we take care from time to time to regulate according to it; accelerating or retarding its motion by an impulse given to its lens before it has lost or gained a whole oscillation. This last part of the proceeding has been suggested by M. Arago, and employed by Captain Freycinet in his voyage round the world. Then it only remains to fix, by observation, the position of the stem upon the arc of amplitudes at the periods of comparison with the chronometer or the clock, and from thence to deduce the fractions of oscillations which the counter could not indicate. These fractions may be obtained from the mathematical law which regulates the motion of the pendulum in each oscillation. If we call 2α the whole amplitude with which the pendulum oscillates, and T the total time which it takes to describe it, also ε the arc which it describes, during the time t, in falling from the extremity of this amplitude, the law of the descent, limited to small amplitudes, gives $\varepsilon = 2\alpha \sin.^2 \left\{ 90° \cdot \frac{t}{\mathrm{T}}, \right\}$ so that, by representing the half amplitude α by 1000 parts, and supposing t successively equal to $\frac{1}{10}$th, $\frac{2}{10}$ths, $\frac{3}{10}$ths of T, or of the duration of a whole oscillation, we obtain for ε the following values.

Values of t in 10ths of the whole Oscillation.	Portions of the Half Amplitude described.
1	48·9
2	191·0
3	412·2
4	691·0
5	1000·0

It would evidently be of no use to push the calculation of these numbers beyond a half amplitude, since they must be symmetrical on each side of the vertical, when the values of the time t are reckoned, as they always can be, from the extremity of the half oscillation in which the pendulum actually is. This being understood, the use of the table is easily explained; for the immediate observation gives the demi-amplitude α at the period of the comparison with the chronometer; it gives also, at this instant, the value of the arc ε, according to the division on the scale of amplitudes to which the stem of the pendulum corresponds. Dividing ε by α, the decimal fraction which will hence result, being multiplied by the number 1000, may be compared with the numbers contained in the second column of the above table; and the first column will immediately give, either directly or by interpolation, the fraction of time corresponding to this position of the stem, a fraction which must be added to the whole number N of the preceding oscillations if the pendulum is on its descent towards the vertical, and subtracted from N + 1 if the pendulum is on its ascent towards the end of the oscillation.

The experiments on the variation of gravity at different places on the earth were not at first made with a free pendulum such as we have now described, but with a pendulum adapted to a clock. It was in this manner that Richer discovered the existence of this phenomenon in 1672, in a voyage which he made to Cayenne by order of the Academy of Sciences, for the prosecution of various researches in physics and astronomy, among the number of which was the measurement of the pendulum. On his arrival at Cayenne, Richer remarked that his clock, the weights of which had not been altered since his departure, had a diurnal rate of going of 2′ 28″ slower than at Paris; and not only did this observation prove the fact of the diminution of gravity, in going from the pole towards the equator, but, if we had known the details, particularly in regard to the relative differences of temperature, we might then probably deduce a more certain and exact measure of this diminution than what can be drawn from the absolute length of the equatorial pendulum, determined by the same Richer at Cayenne, with the imperfect methods which were then in use. We shall not dissemble that this assertion requires some proof; for the mode of observing by clocks appears necessarily subject to great uncertainty, the pendulum's own motion being constrained or modified by the motion of the wheels. But this influence is not, perhaps, in reality so great as one would be led to suppose; in fact, it is not the pendulum, but the weight applied to the clock, which makes the wheels move; the pendulum merely regulates the intermittances in the fall of this weight, by its oscillations, which stop it and set it free by turns; and this alternation is performed by means of the escapement, which now disengages itself from the teeth, and then lays hold of them again. When it is disengaged, the action of the weight which turns the wheel excites it, and accelerates its fall it its descent. But in the ascending half oscillation which follows, the same action confines the pendulum and retards it; so that these two contrary efforts, which both operate with very slight degrees of friction, appear, like the resistance of the air, and every other constant friction, to balance their mutual influences on the motion in each whole oscillation, and merely to limit the amplitude of the arcs in which this oscillation takes place; a limitation which we can easily take into account, by observing the amplitudes, and reducing all the oscillations, by calculation, to the case of their being infinitely small. It would be curious to make experiments on this subject, and it could be easily done; for it would be sufficient to vary the weight applied to a clock, and to see if the variations of amplitude which would result are such that, in paying attention to them, the clock may be brought back to its original rate. Some observations already made indicate the exactness of this restitution, or at least the very near approach to it.

In the travels in Lapland, for example, undertaken by the French academicians in 1736, an excellent clock by Graham was carried out to be employed in determining the variation of gravity. This celebrated artist had constructed it for this purpose, and had done so with very particular care. In order to render it more steadily comparable with itself, he had adapted to it a pendulum, formed of a simple rod of brass, to the bottom of which was affixed a lenticular mass of a constant weight; and he had provided pieces which raised the rod up during the voyage, and kept its summit free from all contact, so that the knife edge could not be altered by any friction against the plane of suspension, although the rod was always at liberty to follow the dilatations and contractions produced by the changes of temperature. Now, in the account of the labours connected with this operation, which Maupertuis has published, under the title of *Figure de la Terre Determinée*, we find, that with the action of the weight usually applied to this clock, it made, at Paris, 86394″·4, during a revolution of the fixed stars, in describing arcs of 2° 10′ on each side of the vertical, while, with a weight twice as small, it made 4″ more, that is, 86398″·4 in the same interval, describing arcs of 1° 15′. Now, if we apply here the correction relative to the amplitude of the arcs, which is

$$\frac{1}{16} \text{N} \sin.^2 \alpha,$$ calling N the number of oscillations, and α the demi-amplitude, we shall then find, that in the first case it is necessary to add 7″·711 oscillations, and in the second 2″·563, to reduce each of them to the case of amplitudes infinitely small, which gives 86402·1 and 86401·0 for the total number of oscillations infinitely small in the two cases. These quantities only differ by 1·1, and as the observations at this period were not carried to a greater exactness than this difference, it would be of no use to look for a more perfect agreement between them. We have still the example of a similar proof made by Graham himself, upon another clock, which he had constructed to determine the variation of gravity between London and Jamaica; an object for which it was really employed, its rate having been observed for this purpose by Graham in London, and at Jamaica by C. Campbell, a skilful observer, and the friend of Bradley. In the account of this operation, which has been given by Bradley himself, in No. 431 of the Philosophical Transactions, it appears that Graham having taken away the weight from this clock, which was 12lb. 10½oz., and having replaced it by another of 6lb. 3oz., the amplitudes of the oscillations, which were at first 3° 30′, were reduced to 3°, and the diurnal rate of the clock slackened by 1½″. Now, if we reduce each of these rates to the case of amplitudes infinitely small, in taking successively for α, 1° 45′ and 1° 15′, we find for the reduction in the first case 5″·03, in the second 2″·6, of which the difference is 2″·4, instead of 1″, which Graham had observed; and as this able artist had not had any other end in view than to prove the small alteration in the diurnal motion by a change of weight so considerable, it is possible that he may not have taken the same pains in determining the temperature and other details of the observation, which he would have done if he had been seeking to determine an element of correction with a perfect accuracy. It appears very probable, then, by these examples, that in clocks constructed in this manner, the action of the weight, transmitted by the wheels, accelerates the proper motion of the pendulum, during each descending half oscillation, as much nearly as it retards it in the ascending half oscillation which follows. So that these opposite modifications seem to compensate each other, at least with a sensible equality, in each complete oscillation. Whence we may conclude, with equal probability, that the greater or less facility in the motions, and the various energies of friction produced by the unequal tenacity of the oil, at different periods and at different temperatures, can have but a very small influence on the proper motion of a pendulum, and which must become quite insensible by employing an oil of tried permanence of constitution; and, above all, by producing artificially, at all the stations, the same fixed temperature as was done by the French academicians in 1736, in their journeys in Lapland, and also by the intrepid English mariners in 1820 in their memorable voyage to the North Pole. But admitting the constancy of the results obtained at the same place by this mode of observation, which, we repeat, still wants to be completely proved by new experiments, it is clear that no other method could be more convenient. For it would be sufficient in every place to prepare the clock; to set it up, with every precaution in levelling which can place it in a state and situation similar to itself; then to compare its rate of going with the diurnal motion of the heavens, either with a small transit instrument, or even by means of a simple telescope, firmly fixed to some immoveable mass, and directed towards a star, the diurnal return of which could be observed with fixed wires stretched in the focus. MM. Breguet instituted a series of experiments on this subject; but as the processes for determining results of this nature cannot be too severely scrutinized, we sincerely wish that other observers would make similar attempts, and publish the results deducible from them.

USE OF THE PENDULUM IN DETERMINING THE OBLATENESS OF THE EARTH, AND THE INTENSITY OF GRAVITY AT DIFFERENT LATITUDES.

According to the theory of universal attraction, if we consider the earth and the planets as having been originally masses in a fluid state, endowed with a motion of rotation round themselves, they must have taken the form of a spheroid, flattened at its poles; and the force of gravity, which is observed at their surfaces, would then be the result of two distinct forces, of which the one is the general attraction, exerted upon each point of the surface by all the particles of matter in the spheroid, according to their masses and distances; and the other is the centrifugal force, excited at the same point by the motion of rotation. But the intensity of the attraction, exerted upon different points of the surface by the whole mass, must be in general variable, as well as the centrifugal force. The union of these two causes, then, must produce in the force of gravity inequalities, which observation may discover. But we may easily rid these inequalities of the effect of the centrifugal force; for this can be calculated for each point, when we know the dimensions of the spheroid, its rotation, and the axis round which it turns. The observations thus reduced present results which are only dependent on the attraction of the spheroid upon which they are made; and they may consequently serve to determine its exterior configuration, as well as the laws of density, by which the attractive matter is distributed through its interior. The remarkable discovery of these relations, between the force of gravity at the surface of the heavenly bodies, and their form, as well as their internal constitution, we owe to Newton; and this great man, in following them out, determined even the value of the oblateness which the terrestrial spheroid ought to have, supposing it elliptical and homogeneous, in order to be in equilibrio with the actual velocity of its rotation. He thus found, that denoting by φ the observed ratio of the centrifugal force to the force of gravity at the equator, the oblateness of the spheroid must be $\frac{5}{4}\varphi$; and as φ, from observation, may be estimated for the earth at $\frac{1}{289}$, or at 0·00346031, there results the oblateness $\frac{5}{4}\varphi = \frac{1}{231}$, or 0·004325, a quantity much superior to the observed value, 0·00326, which shows that the terrestrial spheroid is not homogeneous. But, as this element of measure had not as yet been determined in the time of Newton, he could not draw this consequence. He confined himself, therefore, to the determination of the variations of gravity in the case of the supposed homogeneity, and he found it, as it is in fact, proportional to the square of the sine of the latitude. But he erred in endeavouring to extend these determinations to the case of any ellipsoid, composed of concentric strata of unequal density. For, finding that the observations of the pendulum gave the actual variation of gravity in proceeding from the equator to the pole, greater than the calculation established for the case of homogeneity, he thought that the oblateness ought to increase at the same time with this variation, although the real measures of degrees have since pointed out the inverse of this result; for they agreed in giving a slighter oblateness than 0·004325, with a more considerable variation of gravity. Clairault, in his admirable work on the figure of the earth, was the first to point out this error, which had escaped Newton; and he demonstrated at the same time this remarkable theorem, that, in all the hypotheses, the most probable that can be formed regarding the density of the interior parts of the earth, which must always be supposed most dense towards the centre, there is always such a connection between the fraction which expresses the difference of the axes, and that which expresses the diminution of gravity from the pole to the equator, that, if the one of these two fractions exceeds 0·004325, the second will fall short of it by the same quantity; so that their sum must be always equal to the double of 0·004325, or to 0·00865. In this case, also, the length of the seconds pendulum varies from the equator to the pole, in proportion to the square of the sine of the latitude. Thus, calling λ this length at any latitude L, and A the length at the equator itself, we have in general $\lambda = A + B \sin.^2 L$, B being a constant co-efficient, to be determined by observation. It must be remarked, however, that this result supposes the lengths of the pendulum to be observed at the very surface of the terrestrial spheroid; for, in receding from this surface, although at the same latitude, the intensity of gravity diminishes nearly in proportion to the square of the distance from the centre, and consequently the length of the pendulum must diminish according to the same law. Reciprocally, then, if we have observed this length at any height h above the terrestrial surface, and that we have found for it a value expressed by l, a being the radius of the earth at this latitude, the length reduced to the level of the sea will be $\frac{l\,(a+h)^2}{a^2}$, or $l + \frac{2hl}{a} + \frac{lh^2}{a^2}$. But this reduction may be simplified, by considering that, on account of the small height to which we can rise above the earth's surface, $\frac{h}{a}$ is always a fraction so excessively small, that the first power of it is sufficient to be used. So that, limiting ourselves to this order of approximation, the reduced length will become $l + \frac{2hl}{a}$. The term $\frac{2hl}{a}$ forms, then, the correction which the experiments require that they may be reduced to the level of the sea, and thus rendered comparable with each other. Such is, in fact, the mode of reduction generally employed; but we must remark, that it is itself subject to uncertainty. For the mountains on which we ascend attract the pendulum by virtue of their own mass; in consequence of which, it becomes necessary to pay attention to this attraction, that the reductions may be made rigorously exact, instead of applying the bare formula, which supposes the observations to have been made in the open atmosphere. But this is an inconvenience which is unavoidable; for it is impossible to calculate exactly the peculiar attraction of the masses on which we operate, since this would require the knowledge of their relative density, and even of the arrangement of the materials which enter into their composition. But, as we cannot avoid this uncertainty, we must endeavour to render it as small as possible, by making our observations as near the level of the sea as we are able. We must then recollect, that, by ascribing at the highest station the whole of the force of gravity to the sole and distant action of the earth, we suppose it to be more powerful than it really is. So that, by reducing it, on this hypothesis, to what it would really be if it had been observed at the level of the sea itself, we commit a double error; the mountain's own attraction tending, in this second case, by its contrary direction, to weaken the effect of gravity, which it had before augmented. Fortunately, the excessive smallness of the highest mountains, compared with the mass of the globe, must diminish extremely their relative influence, and render equally minute the errors which may arise from neglecting it.

To determine, now, the co-efficients A and B of the general formula, we shall employ the oblateness 0·00326, or $\frac{1}{306{\cdot}75}$, which M. Laplace has obtained by submitting to a general and profound discussion the measures of the terrestrial degrees, and the lunar inequalities depending on the oblateness of the earth. We shall join to it the length of the simple pendulum of sexagesimal seconds, found by Biot at the station of Unst, a length which, we think, may be considered as one of the most certain that has been observed; first, because having been the last of the observations made by Borda's method, it must have been taken with all the precautions suggested by preceding experiments; secondly, on account of the great number of series from which it results, these being fifty-six in number, and made with different rules, and pendulums of unequal lengths, which all agreed in assigning for the definitive result values differing excessively little from each other; and, lastly, from the perfect agreement which is found between it and the results of the observations of Captain Kater. This single absolute length, together with the oblateness 0·00326, will suffice for determining the two constant quantities A and B of the general formula, which expresses the length of the pendulum at any latitude. Now, according to this formula, the length of the pendulum at the equator, where L is nothing, is equal to A, and at the pole, where L = 90°, it is $A + B$. So that $\frac{B}{A}$ is the relation of the total variation of the pendulum to its absolute length at the equator; a ratio which is the same as that of the increments of gravity to the absolute force of gravity itself. Adding, then, $\frac{B}{A}$ to the oblateness 0·00326, we shall have, by the theorem of Clairault, the following condition, $\frac{B}{A} + 0{\cdot}00326 = 0{\cdot}00865$, whence we obtain $B = A \cdot 0{\cdot}00539$, and consequently $\lambda = A\,(1 + 0{\cdot}00539 \cdot \sin.^2 L)$. Now we have seen above, that at the station of Unst, in latitude 60° 45′ 25″, the length of the sexagesimal seconds pendulum determined by the observations of Biot was $\overset{m\,m}{994}{\cdot}943105$. The height of this station was only 9^{m} above the level of the sea, which gives for the reduction $+\,0{\cdot}^{mm}002818$. Whence there results, at the level of the sea, the height $\overset{m\,m}{994}{\cdot}945923$. Putting this value, then, and that of L in the formula, the co-efficient A is determined, and we find $A = \overset{m\,m}{990}{\cdot}879660$, consequently $B = 5{\cdot}340843$; which gives for any latitude L,

$$\lambda = \overset{m\,m}{990}{\cdot}879660 + \overset{m\,m}{5}{\cdot}340841 \sin^2 L.$$

If we wish to reduce this formula to English inches, all the terms must be multiplied by $\frac{39{\cdot}37079}{1000}$, and then

$$\lambda = \overset{in.}{39}{\cdot}0117150 + \overset{in.}{0}{\cdot}2102732 \sin.^2 L.$$

Finally, if we wish to reduce it to the decimal pendulum employed by the French observers in their calculations, we must multiply the terms by $\left(\frac{864}{1000}\right)^2$, the ratio of the decimal to the sexagesimal pendulum. We then have

$$\lambda = \overset{m\,m}{739}{\cdot}687686 + \overset{m\,m}{3}{\cdot}986917 \sin.^2 L.$$

If we calculate from this last formula the lengths of the decimal pendulum for the stations where the French observers have operated, from Formentera to Unst, and compare them with their results, we obtain the following table.

Names of the Places.	Names of the Observers.	North Latitudes.			Length of the Decimal Pendulum at the Level of the Sea.		Excess of Calculation.
					By Calculation.	By Observation.	
					mm	mm	
Unst	Biot.	60°	45′	25″	742·723136	742·723136	0·000000
Leith Fort	Biot, Mudge.	55	58	37	742·426416	742·413435	+0·012981
Dunkirk	Biot, Mathieu.	51	2	10	742·098066	742·077030	+0·021036
Paris	Biot, Mathieu, Bouvard.	48	50	14	741·947360	741·917490	+0·029870

Bordeaux	Biot, Mathieu.	44	50	26	741·670048	741·608720	+0·061328
Figeac	Biot, Mathieu.	44	36	45	741·654181	741·612280	+0·041901
Formentera	Biot, Arago, Chaix.	38	39	56	741·243950	741·252000	—0·008050

The progression of the deviations contained in the last column of this table shows, in proceeding from the north to the south, a progressive decrease of gravity, greater in a slight degree than the elliptical figure requires; a result which had already been remarked in regard to Scotland and England by Captain Kater. It may be observed here, that the absolute value of this variation for Unst, Leith, and Dunkirk, agrees exactly with that which Captain Kater has found, or what could be deduced from his experiments. But the same effect is observed to continue throughout France, being most sensible at the station of Bordeaux. It becomes less even at Figeac, situated more inland, and on a more solid base. It again becomes nothing at Formentera, where the deviation of the formula compared with observation is $\frac{8^{mm}}{1000}$ in a contrary direction, which would seem rather to indicate a slight local excess in the intensity of gravity. This singular anomaly, which is so stated, in regard to the force of gravity, throughout the terrestrial arc which extends over all this part of Europe, is, without doubt, owing to peculiarities in the geological constitution of the countries which are situate on it; and it appears by this example, how well the observations of the pendulum are adapted for pointing out the irregularities of this constitution. But, for this purpose, the observations must possess so great a degree of exactness that the peculiar uncertainties to which they are liable may be, as we may suppose they were in those which we have employed, much smaller than the variations of constitution which they are intended to indicate. Here it may be remarked, that the part of France where these variations are the most sensible, are precisely the same where there were found, by Delambre's observations, the greatest anomalies in the lengths of the degrees.

From the preceding formulæ may be deduced the variation in the diurnal rate which a compound pendulum, of an invariable form, must present when carried to different latitudes. If we denote by N, N the number of oscillations of this pendulum at two different stations, where the lengths of the simple seconds pendulum are λ, λ′, we have shown above that $\frac{\lambda'}{\lambda}\ \frac{N'^2}{N^2}$, whence $N'^2 = \frac{\lambda'}{\lambda} . N^2$. Now, calling L, L′ the latitudes of the two stations, the above formulæ give the values of λ and of λ′, as well as their relations; substituting, then, these values in the preceding equation, we obtain $N'^2 = \frac{A + B \sin.^2 L'}{A + B \sin.^2 L} N^2$; an expression by means of which we can calculate N′ when we know N.

The total variation of gravity from the equator to the pole is so inconsiderable that the difference between the numbers N, N′ is always very small compared with these numbers themselves. This difference, then, is the element which we must try to put in evidence in the formulæ. But nothing is easier; for, if we denote it by *n*, so that N′ is represented by N + *n*, the preceding equation will become

$$N^2 + 2nN + n^2 = \frac{A + B \sin.^2 L'}{A + B \sin.^2 L} . N^2.$$

Whence we deduce

$$2nN + n^2 = \frac{B \sin. (L' + L) \sin. (L' - L)}{A + B \sin.^2 L} . N^2;$$

and resolving the value of N into a series,

$$n = \left\{ \begin{array}{l} \frac{B \sin. (L' + L) \sin. (L' - L)}{2 (A + B \sin.^2 L)} . N \\ - \frac{B^2 \sin.^2 (L' + L) \sin.^2 (L' - L)}{8 (A + B \sin.^2 L)^2} . N, \&c. \end{array} \right\}$$

But from the value of the oblateness which we have adopted, we have seen that B is equal to 0·00539 A. Substituting this value in our series, it becomes

$$n = \left\{ \begin{array}{l} \frac{0{\cdot}00539\ N \sin. (L' + L) \sin. (L' - L)}{2 (1 + 0{\cdot}00539 \sin.^2 L)} \\ - \frac{0{\cdot}000029\ N \sin.^2 (L' + L) \sin.^2 (L' - L)}{8 (1 + 0{\cdot}00539 \sin.^2 L)^2}, \&c. \end{array} \right\}$$

The second term will be almost always insensible, and it will be quite needless to take in any of the following ones.

To show the use of this formula, we shall apply it to the following observations, which belong to the most distant countries on the earth.

The experiments of Captain Sabine were made with two pendulums applied to two different clocks, the results of which have agreed very well in their relations. We have only stated here the mean of these results. The observations of Maupertuis, Clairault, and Lemonnier, were made by a process of the same kind, but with a single clock by Graham. In these two expeditions the observers produced artificially at the second station the same temperature as at the first. In the operation by Campbell, the same pains were not taken; but in Bradley's computations, an allowance was made according to the indications of the thermometers. The experiments of Captain Freycinet were made on detached pendulums, the rate of which, first determined by Arago, Mathieu, and himself, at the Royal Observatory of Paris, was compared in the voyage with well-regulated chronometers, making allowance, by calculation, for the changes of temperature. The smallness and the irregularity of the differences which are found between the results of these different experiments, and the numbers given by the formula, show that the latter is the general expression of them, modified only by the accidental variations which may be occasioned in each place by small differences of density in the neighbouring strata of the surface of the earth. The formula being grounded upon the oblateness 0·00326, or $\frac{1}{306{\cdot}75}$, its agreement with the facts proves that this value of the oblateness, if not rigorously exact, is at least a very near approximation, and is, besides, common to the two hemispheres of the globe, since the observations of Captain Freycinet in the southern hemisphere, at the Cape of Good Hope, are as correctly represented by it as the observations made in the northern hemisphere. This puts an end, then, to the notion entertained after the measurement of the degree by Lacaille in this part of the globe, that the southern hemisphere was more oblate than the northern; a notion, however, already much weakened by the agreement of the oblateness observed in this latter hemisphere, with that which was deduced from the inequalities of the moon; since the motion of this satellite must be influenced by the mean of the two ellipticities, if they were different; but it was nevertheless of consequence to see this suspicion wholly extinguished, as it is now by Freycinet's observations.

The general experiments on the length of the pendulum which we have above described, being verified by the different observations by which we have compared them, will serve to determine the intensity of gravity, whether absolute or relative, on any of the places of the terrestrial globe. For, calling λ the length of the simple pendulum, which makes its oscillations in a second of time in a given place, and denoting by g the double of the space which gravity makes bodies describe in their fall in the same place, and during the same interval of a second, the fundamental formula of oscillations, infinitely small, gives $1'' = \pi\sqrt{\frac{\lambda}{g}}$, consequently $g = \pi^2\lambda$, π being the ratio of the circumference to the diameter, or 3·14159. But we have already given for any latitude the value of λ expressed in millimetres and in English inches, taking for the unity of time either the decimal or the sexagesimal second. Multiplying these expressions by the square of π, we shall have the value of g for the same latitude, and the same kind of unity of time which may be chosen.

It may be objected, that we have not made use of the lengths of the simple pendulum observed under the equator by Bouguer, and detailed in his work on the figure of the earth. The reason is, that, notwithstanding the ability of Bouguer as a philosopher and an observer, and the infinite pains which he took in his measurements of the pendulum, it appears to us, on account of the nature of the processes he made use of, that they are too inexact to be employed with advantage. The method of Bouguer consisted in forming a sort of simple pendulum, with a very small weight suspended to a stem, the other extremity of which was attached to a pincer fixed into a solid wall. He made this little pendulum always of the same length, by comparing it with an iron rule, which served him for a standard; after which he determined the value of its oscillations by comparing its rate with that of a clock regulated by the heavens. But M. Laplace has justly remarked, that the bending of the stem at the point of suspension, where it is inserted into the pincer, must produce the same effect on the oscillations as a contraction in the wire; so that the length, measured in a state of repose, must be too great, and would appear to give the pendulum too long. This effect, indeed, must have been produced on all the lengths given by Bouguer, since they were all observed in the same manner. From that it would seem that these observations might at least be employed in comparison with each other, and in that case give exact ratios. But the process by which Bouguer judged of the length of his little pendulum, and compared it with his standard rule, appears to us not accurate enough for giving a sufficient certainty in his results. For it consisted in laying this rule close to the pendulum, placing its upper end in contact with the point, and judging of its equality by the eye, in comparing it with the pendulum at its lower extremity. But no one, by such an operation, can answer for an exactness greater than $\frac{5}{100}$ths of a line. Now $\frac{5}{100}$ths of a line being equal to $\frac{1}{10}$th of a millimetre, such an error, with the methods now actually employed, would be accounted gross, and such indeed as, with the least attention, it is quite impossible to commit. These results cannot, then, be compared with the observations which are made now; and, unfortunately, the same remark applies with equal justice to the measurements of the absolute lengths of the pendulum which were made about the same period, as well in France as in various other parts of the globe. We think it extremely probable, that to the want of exactness in the methods employed at that time may be ascribed, at least in a great measure, the strange anomalies observed by Grischow in the lengths of the pendulum, in the neighbourhood of St Petersburg, between stations very little distant from each other; anomalies so much more justly suspected, since the different instruments employed by Grischow to establish them are far from agreeing with each other. Nevertheless, for removing entirely all suspicion with regard to a point so important, it would be a useful undertaking to repeat these experiments in the same places where Grischow's observations were made; employing for this purpose our present much more accurate methods. (S. S. S. S.)

Much has been done in this department of science since the preceding part of this article, which was written by M. Biot for the Supplement to the sixth edition of this work, was published. This took place not long after a most important addition had been made both to the instruments of research and to the methods of experimenting, by the invention, or at least the construction and application, of the convertible pendulum.

IV.—DETACHED PENDULUMS.

Although Professor Bohnenberger, in a treatise on astronomy, published at Tübingen in the year 1811, had suggested that the length of the seconds pendulum might be obtained by means of Huygens's theorem, yet he seems to have done nothing towards putting the scheme in practice; nor had any notice of such a suggestion reached Captain Kater till fully eight years after he had devised and executed his valuable experiments, as described in the Philosophical Transactions for 1818. These form a new era in the history of the pendulum, and have greatly increased the interest and importance which, only a few years before, had begun to be attached to researches on this subject, and which have ever since continued to increase. This is evinced, not only by the repeated and valuable labours of several of the most distinguished mathematicians and experimentalists of the present age, but also by the numerous scientific voyages that have been undertaken by various governments, with the view of ascertaining and comparing the results of different pendulum experiments made in various parts of the world, and thence to determine the true figure of the earth. The most valuable and extensive experiments of this sort are those made by Major Sabine and those by the late Captain Henry Foster, in almost every practicable latitude, and embracing a greater variety and range of temperature than those of any other experimentalist. As is the usual method among the English experimenters, invariable pendulums, which had been first observed in London to ascertain the number of vibrations made there per day, were afterwards observed in the same manner at all the stations, and similarly again on returning to London. In this manner, without regarding the absolute force of gravity at any one place, the proportion of it at different places is found probably with greater accuracy than by any other method. With the French philosophers, however, it is more usual to observe the absolute length of the seconds pendulum at every station. In this manner they have experimented in a great variety of places; but in some cases they have also employed invariable pendulums, which are the same with those called "pendulums of comparison" in the preceding article; for the term *invariable* does not refer to any compensation for temperature, &c., but merely implies that the effective length is never interfered with, by shifting or altering the positions or magnitudes of any of the parts. In this way the results at different stations are more capable of being compared.

It is not many years since such results, especially the number of vibrations which are made in a mean solar day, whether by the same or by different pendulums, were considered as strictly comparable with each other, provided only they were reduced, by means of certain hypothetical rules, to what it was believed they should have been under the following circumstances: 1*st*, at the mean level of the sea; 2*d*, in a vacuum; 3*d*, in indefinitely small arcs; and, 4*th*, at a common standard of temperature.

The late Dr Thomas Young, however, at length demonstrated that the formerly-received formula for the reduction to the level of the sea is in most cases too great. M. Bessel next questioned the old formula for the reduction to a vacuum, as having the contrary fault of being too small. This he had inferred from some very far-fetched experiments; but that the old correction was really too small, has since been amply confirmed by the direct experiments of Major Sabine and Mr Baily. In this reduction to a vacuum they had all to a certain extent been anticipated by the Chevalier Du Buat, who has treated the question experimentally, and at great length, though in a much less satisfactory manner, in his *Principes d'Hydraulique*, second edition, 1786, and third edition, 1816. But his researches having appeared before any great interest had been taken in this question, they were till lately almost totally overlooked and unknown. The like may be said of some hints given by Newton, and well deserving of notice, in his *Principia*, lib. ii. prop. 27, cor. 2. Fortunately, this defect in the old formula for the reduction to a vacuum has not been productive of any considerable errors in the determinations of the proportions of the force of gravity at different places. In the Philosophical Transactions for 1831, Major Sabine has described a variety of experiments, which have led him to question the accuracy of the usual formula for the reduction to indefinitely small arcs. He had previously, in his work on the figure of the earth, pointed out the discordant results arising from the use of different agate planes with the same knife-edge; and had also stated his decided opinion on the powerful effects of certain geological strata, or even of an increase of buildings, in the immediate neighbourhood of the pendulum. Mr Baily, again, in the Philosophical Transactions for 1832, has gone much farther, in having pointed out great discordances between experiments executed with the *same* knife-edge of the *same* pendulum, and on the *same* plane. He likewise acknowledges, that to whatever cause the observed anomalies may be owing, he has, during a long course of experiments on various pendulums, at different seasons of the year, and under a variety of circumstances, frequently met with discordances that have baffled every attempt at explanation by any of the known laws applicable to the subject; and other persons, also, who have had much practice in such experiments, have occasionally met with anomalies for which they have been as unable to account. As it is desirable, however, that these difficulties should be cleared up, if possible, and as every information connected with so important a subject, founded on such delicate experiments, must add to our means of removing them, we shall by and by give a summary account of the results of a variety of experiments made by Major Sabine and Mr Baily, with pendulums of various forms and constructions, immediately bearing on the discordances in question.

It is evident that till two pendulums can be constructed which will always give precisely the same results, cleared of all these discordances, the important problem of determining the length of the simple pendulum cannot be considered as fully solved; neither can the observations made by different experimentalists, in different parts of the globe, with different pendulums, be strictly and directly comparable with each other. We have, it is true, two pendulums, differing widely in form and construction, and yet agreeing surprisingly in their results, viz. Borda's and Kater's. But although this evinces the talent and skill of the distinguished persons who made the experiments, it should not be forgotten that the reductions to a vacuum were, in both cases, made agreeably to the old formula; and that since the date of M. Bessel's important researches on this subject, which indicate the necessity of revising the computations of all preceding experiments, no rigid comparison of the results has yet been repeated. The amount of the additional corrections for Borda's pendulum and for that of Kater differ materially, as will be shown in the sequel, so that we are as yet ignorant whether the results of any two pendulums that have ever been differently constructed are in strict accordance with each other; nor, until this is practically accomplished and repeated, can the true length of the seconds pendulum be considered as satisfactorily determined.

eduction
o the level
f the sea.

It had long been the practice to make allowance for the height of any station above the level of the sea, without taking into account the attraction of the elevated parts themselves. Dr Young showed that this was far from being correct; but no one has yet been able to estimate the exact amount of the error, nor is it likely ever to be attained. It is, however, obvious, that if we were raised on a sphere of earth a mile in diameter, its attraction would be about $\frac{1}{8000}$ of that of the whole globe; and instead of a reduction of $\frac{1}{2000}$ in the force of gravity, we should obtain only $\frac{3}{8000}$, or three fourths as much. Nor is it at all probable that the attraction of any hill a mile in height would be so small as this, even supposing it to have been only two thirds the mean density of the earth. That of a hemispherical hill of the same height would be fully one half more than the sphere, or would exceed its attraction in the ratio of 1·586 to 1. And it may be easily shown that the attraction of a large tract of table-land, considered as an extensive flat stratum a mile in thickness, would be three times that of a sphere a mile in diameter, or about twice as great as that of such a sphere having the mean density of the earth; so that for a place so situated the allowance for elevation would be reduced to one half; and, in almost any country that could be chosen for the experiment, it must remain less than three fourths of the whole correction deduced immediately from the reciprocals of the squares of the distances from the earth's centre. From Dr Young's view of the subject, it also appears that the correction for the elevation above the sea will vary, according to the nature of the eminence, and also its density, from one half to three fourths of the quantity which it was customary to deduce from the inverse ratio of the squares of the distances from the earth's centre. Thus, if the mean density of the earth be taken at 5·5, and that of the matter surrounding the station at 2·5, the quantity deduced from the duplicate distances should be multiplied by $\frac{66}{100}$ to obtain the correction for a table-land, and by $\frac{7}{10}$ for that of an eminence of moderate declivity. (Philosophical Transactions for 1819.)

Perhaps some estimate might be formed of the local effects of a cavity, or of a circumscribed mass of any peculiar density, and hid under the surface, by swinging the pendulum at several places around the principal station, and not far from it; and it might even throw some light on the subject to swing the pendulum both in the plane of the meridian and at right angles to it.

In 1824 a series of pendulum experiments was made by Carlini at the summit of Mont Cenis, to ascertain the diminution of gravity at the height of a geographical mile, as detailed in the Milan Ephemeris. He obtained for the mean density of the earth 4·39; but the changes which experiment has shown to be necessary on the elements of reduction throw some doubt on its value. Mont Cenis is peculiarly favourable for such experiments, as it forms nearly a segment of a sphere, of which the chord is about eleven geographical miles, and the versed sine one mile. It consists of calcareous rocks whose mean density is 2·66. The mountain Schehallien, on the attraction of which Maskelyne and Hutton made experiments, has since then undergone a mineralogical survey; and from the more correct data so obtained some alteration has been made on the original numerical results. The calculations of Cavendish's experiments on attraction were also corrected by the late Dr C. Hutton, as detailed in the Philosophical Magazine for July 1821. Professor Reich of Freyberg has recently repeated Cavendish's experiment, though in some respects on a smaller scale; for the larger leaden sphere was only 7·75 inches in diameter, and he used only one such sphere at a time. The result gave 5·44 for the mean density of the earth, and an iron ball of the same size gave 5·43. Cavendish's experiment is also about to be repeated in this country, and a new proposal will be noticed afterwards.

Reduction
to a vacuum.

Newton and Du Buat had, as already mentioned, made it plain that the air affects in several ways the motions of pendulums; and more recently M. Bessel has called attention to the subject by his very interesting work on the pendulum,[1] in which he has shown that the usual formula for the reduction to a vacuum, as far as the specific gravity of the moving body is concerned, is very defective, and by no means expresses the whole of the correction which ought to be applied; in fact, that a quantity of *air* is also set in motion by and adheres to the pendulum (varying according to its form and construction), and thus a *compound pendulum* is in all cases produced, the specific gravity of which will be much less than that of the metal itself. He observes, that if we denote by m the mass of a body moving through a fluid, and by m' the mass of the fluid displaced thereby, the accelerating force acting on the body has, since the time of Newton, been considered equal to $\frac{m - m'}{m}$. This formula is founded on the assumption that the moving force which the body undergoes, and which is denoted by $m - m'$, is confined to the mass m. But it must be distributed not only over the moving body, but on all the particles of the fluid set in motion by that body, and consequently the denominator of the expression denoting the accelerating force must necessarily be greater than m. M. Bessel then enters into a mathematical investigation of the principles from which the results of his experiments are deduced, and at length concludes, that a fluid of very small density surrounding a pendulum has no other influence on the duration of the vibrations than that it diminishes its gravity and increases the momentum of inertia. When the increase in the motion of the fluid is proportional to the arc of vibration of the pendulum, this increase of the momentum of inertia is very nearly constant; in all other cases it will depend on the magnitude of that arc.

---

[1] *Untersuchungen über die Länge des einfachen Secundenpendels*, 4to, Berlin, 1828.

In the *Mémoires de l'Academie*, tome xi. 1832, and in the *Connaissance des Tems* for 1834, Baron Poisson has endeavoured to investigate the relations between the simultaneous movements of a pendulum and the surrounding air, and has deduced that the loss of weight of a sphere exceeds by one half the weight of air it displaces. Such investigations are, however, unavoidably mixed up with assumptions. The resistance of the air to a ball pendulum has also been considered by M. Plana, in a memoir published at Turin in 1835, in which the case of an incompressible fluid is first discussed, and then that of an elastic fluid; and from both the author concludes, as Poisson had done, that the loss of weight of the sphere exceeds by just one half the weight of the fluid it displaces. The question, however, has not yet received a satisfactory solution, since theory has hitherto failed to account for one of the leading circumstances of the case, viz. that the co-efficient of resistance is different for spheres of different diameters. This difference, it appears, would equally exist whether the balls vibrated in a confined apparatus or in free air. The vibrations of a pendulum in fluid media have likewise been investigated by Mr Green, in the Transactions of the Royal Society of Edinburgh, vol. xiii.

In the theoretical researches on this question, it does not seem to be considered, that since each vibration of a pendulum in air tends to create a current of that fluid, against which it is to return in the succeeding vibration, the alternating motion of the pendulum must subject it to a very different and much greater resistance from the air than if its motion were continuous and not reciprocating. But on what principles a formula could be framed to express the velocity and mass of such currents, or their resistance, we cannot pretend to say. No doubt, if the space in which the pendulum vibrates be very confined, that will farther affect the result. Such considerations seem to set at defiance every attempt at framing any thing beyond an empirical formula for these reductions.

But those experiments and researches, though very imperfect, are sufficient to show that the amount of the correction will not only vary according to the size, figure, weight, and density of the moving body, but also, that in the case of the convertible pendulum (except, perhaps, when it makes the fewest vibrations possible) the correction will not be the same for the two knife-edges, and consequently that a pendulum which has been made convertible in air, will not be so when tried in a vacuum. It becomes, therefore, of importance to know how far the differently constructed pendulums used by various experimentalists are affected by this newly-discovered principle, in order that their results may be strictly comparable with each other. The amount of the required correction, however, cannot in the present state of the question, and most probably never will, be determined by calculation founded on any satisfactory theory, but must for every pendulum be ascertained by actual experiment. The most direct, and perhaps the only certain method of effecting this, appears to be by swinging the pendulum in a vacuum; although M. Bessel himself, on account of some undefinable doubts which he entertained regarding it, adopted two other and very different methods of experimenting for this purpose. The first was by swinging in air one sphere of brass and another of ivory, each being about 2·14 inches in diameter, and suspended by a fine steel wire; the other method consisted in swinging the same brass sphere, first in air and then in water. The results persuaded him that the usual reduction to a vacuum was much too small. The first method, which he considered the preferable one, gave 1·956, and the second 1·625, as the factor by which the old formula should be multiplied, in order to obtain the true correction. To such experiments we can attach very little importance, because these numbers are still reached nearly as much through the medium of a hypothesis as the old formula. What the swinging of a ball in water has to do with the rate of a pendulum in a vacuum, we cannot pretend to see. The experiments of Du Buat were very similar to those of M. Bessel, but if possible still more objectionable.

Old co
rectio

The old correction for reducing the number of vibrations to a vacuum had been deduced from the relative weights of the air and of the pendulum by means of the formula

$$N \times \frac{1}{2\left(\frac{S}{\sigma}-1\right)} \times \frac{\beta'}{\beta} \times \frac{1}{1+(a+\mu)(t'-t)},$$

where N is the number of vibrations in a mean solar day, S the specific gravity of the pendulum, σ the specific gravity of air, μ the expansion of mercury, and a the expansion of air for one degree, β' the height of the barometer, and t' the temperature during the experiments, β and t the standard pressure and temperature for computing the specific gravities. But in this, S ought not, as hitherto, to denote the mean specific gravity, as determined in the usual manner, for the pendulum, when at rest, if it consists of several parts, whose specific gravities are different; for in all such cases we should compute the *vibrating* specific gravity of the mass in the following manner. Let d', d'', d''', &c. denote the distance of the centre of gravity of each body respectively from the axis of suspension (these being positive if below, and negative if above it); w', w'', w''', &c. the weight in the air of each body; s', s'', s''', &c. their specific gravities determined in the usual manner. Then will the required *vibrating* specific gravity of the pendulum be

$$S = \frac{w'd' + w''d'' + w'''d''' +, \&c.}{\frac{w'd'}{s'} + \frac{w''d''}{s''} + \frac{w'''d'''}{s'''} +, \&c.}$$

which is Professor Airy's formula.

The other parts of the above formula forming the old correction are so far erroneous, that no account is taken of the effect of the air set in motion by and accompanying the pendulum, as if adhering thereto; and which is now found to influence the result very materially. Mr Baily thinks, that in the case of the gridiron pendulum, it may be a matter of doubt whether the air between the vertical rods may not diminish their specific gravity, when considered as a vibrating body.

Major
bine's
riment

Early in the year 1828, a proposal was made to the late Board of Longitude, that, on account of the uncertainty in the extent of the defects which M. Bessel had discovered in the old formula for reducing the vibrations of a pendulum in air to what they should be in a vacuum, it would be of great importance to submit the question to the most direct experiment, by the construction of an apparatus in which a pendulum might be alternately vibrated in air of full atmospheric pressure, and in air rarefied nearly to a vacuum. This proposal having been favourably entertained by the Board, orders were given for fitting up an apparatus for this purpose at the public expense, and which was ably executed by Mr Newman, under the direction of Major Sabine, by whom it was to be used; but, that it might also be useful to others who might wish to avail themselves of it for similar purposes, a place was allotted for it in the Royal Observatory at Greenwich. This apparatus, or chamber for forming the vacuum, consists principally of six pieces, exclusive of the iron frame by which the suspension is fixed securely to the wall of the apartment. The pedestal, which has a broad exterior base, is of cast-iron, forming a cylindric dish one foot wide within, and the same in depth; and from a hole in its side proceeds a pipe, which communicates with an air-pump, but can be closed at pleasure by a stop-cock. The three next pieces of the chamber rising in succession above the pedestal are open-ended glass cylinders, each being fifteen inches in depth, and slightly tapering upwards. These and the pedestal have their rims ground to fit upon one another. The suspension-piece, which is the next above the three glasses, is a metal plate, having holes to receive the screws of the bed containing the agate planes, and to admit the pendulum to its place. It is surrounded by a circular metal ring, the outside of which forms a part of the exterior of the apparatus, and the upper and lower surfaces are ground so as to form close joints with the rim of the glass cylinder beneath, and with a bell-glass, which is the sixth piece, closing in the top of the chamber. The ring surrounding the suspension plate is perforated, to admit, through a stuffing-box, a screw, which acts on an inclined plane beneath the Y's, serving to raise the pendulum by means of the Y's, and to lower it again on the planes. The pedestal cylinder is also perforated, to admit, through a stuffing-box, a wire with a cross piece at the extremity, for the purpose of stopping or of giving fresh impulse to the pendulum. A clock was placed about eighteen inches behind the centre of the apparatus, and the coincidences of the two pendulums were observed by means of a telescope about sixteen feet distant. A detached diaphragm, having a vertical opening, the sides of which, viewed from the telescope, were tangents to the disc on the pendulum of the clock, was placed between the apparatus and that disk. The pendulum was first vibrated in air of full pressure, then in rarefied air, and lastly in that of full pressure. A mean being then taken between the two series in the air, was compared with that in the rarefied medium. The result was thus independent of the daily rate of the clock. It was also carefully ascertained, by experiments made on purpose, that, with a free communication between the interior of the apparatus and the external air, the pendulum made just the same number of vibrations as when the glasses were removed altogether.

The following table contains the final results; but for the details we beg to refer to the Philosophical Transactions for 1829, where they are given at great length.

No.	Temperature.	Inches.	Inches.	Vibrations.	Vibrations.	Difference.
1	72°·01	7·08	22·765	7·38	7·42	+·05
2	69 ·70	1·71	27·721	9·065	9·08	+·015
3	35 ·89	2·38	27·459	9·54	9·66	+·12
4	32 ·37	3·59	26·138	9·17	9·26	+·09
5	36 ·40	0·653	29·109	10·38	10·24	—·14
6	35 ·65	14·116	16·080	5·705	5·65	—·055
7	38 ·10	...	30·193	10·525	10·575	+·05
8	41 ·25	...	30·113	10·560	10·48	—·08
Means	45 ·17	...	26·197	9·042	9·046	+·005

The third column is the pressure within the apparatus by the gauge; the fourth the difference between that of the barometer and the third; the fifth the observed retardation, or the difference between the number of vibrations made per day under the full pressure and that in column third; the sixth the retardation by calculation; and the seventh their difference.

In the seventh and eighth experiments, a near approach had been made to a vacuum by repeatedly filling the apparatus with hydrogen, and then exhausting it as far as practicable. At the same time experiments were made on the rate of the pendulum in hydrogen having the full atmospheric pressure, for the purpose of comparing it with the rate in air. From one experiment, it appeared that at the same height of the barometer, 30·193 inches, the pendulum made 8·515 vibrations per day more in hydrogen than in air, the temperature of the gas being 39°·32, and of the air 38°·1. From another experiment it appeared, first, that at nearly equal heights of the barometer (30·120 for hydrogen, and 30·113 for air), the pendulum made 8·56 vibrations more in hydrogen at 39°·75, than in air at 41°·25; second, that it made 1·95 vibration per day more in hydrogen of 0·872 inch pressure, than when the pressure of the gas was 30·120. Hence 1·95 vibration corresponds to a difference of 29·248 inches pressure of hydrogen, and, therefore, two vibrations per day will be the reduction to a vacuum for hydrogen of thirty inches pressure at 40°. The retardation of the pendulum in air is to that in hydrogen as 10·41 to two, and as 10·55 to two, when both are reduced to the same pressure and temperature; the mean being as 5·24 to one nearly. Now, the densities of air and hydrogen being nearly as thirteen to one, shows that the retardation in different elastic fluids is not in the simple ratio of their densities. Major Sabine supposes it to indicate an inherent property in the elastic fluids, analogous to that of viscidity in liquids, of resistance to the motion of bodies passing through them independently of their density.

But perhaps a less hypothetical reason might be given why hydrogen gas should occasion a greater retardation than one thirteenth that of air of full pressure. The retardation of air in these experiments appears to be as its density; thus, for example, air rarefied thirteen times should only offer one thirteenth of the retardation of air of full pressure. Now, it has been shown in the article Hygrometry, vol. xii. page 118, that the specific heat of a given volume of air is as its density; so that air which is thirteen times rarer will emit only one thirteenth as much heat on being compressed. But, from Dr Haycraft's experiments, it appears that, under equal volumes, pressures, and temperatures, hydrogen and air have equal specific heats. Consequently hydrogen of full pressure, on being compressed by the motion of the pendulum, will emit thirteen times more heat than air equally rare would do on being so compressed; and the like may be said of any cold due to the rarefaction occasioned by the motion of the pendulum. Here, it is true, the changes of temperature in the two gases themselves would still be equal, were it not that the materials of the apparatus will have far more power to check any fluctuations or undulations of temperature in the rarefied air than in the hydrogen, which is thirteen times better supplied with sensible heat, and which, therefore, having the equilibrium between the temperatures of its different parts more disturbed by the motions of the pendulum, will be thereby put into a state of greater commotion than the rarefied air, and consequently will so much the more disturb the free motion of the pendulum.

From the mean of the results in the above table we have 9·042 vibrations per day as the reduction to a vacuum of the invariable pendulum vibrating in air of 45° under a pressure of 26·2 inches, and consequently in the same proportion we have 10·36 vibrations under a pressure of thirty inches; but which, if reduced to 32°, by multiplying it by $\frac{448 + 45}{448 + 32}$, as explained below, will be 10·64 vibrations. As we have no information regarding the humidity of the air when Major Sabine made his experiments, we have taken it to be perfectly dry, which it never is. The old "correction for buoyancy," as formerly computed, would have been 6·26 vibrations, which is less than 10·36 in the ratio of one to 1·655, and less than 10·64 in the ratio of one to 1·7.

Now, from the principles developed in the article Hy-

GROMETRY, vol. xii. p. 131, it appears that if the specific gravity of dry air under the pressure P and at the Fahrenheit temperature T be reckoned unit, the specific gravity of a mixture of air and aqueous vapour whose joint pressure is p and temperature t will be

$$\frac{p - \cdot375f}{P} \times \frac{T + 448}{t + 448},$$

where f is the force of the vapour. If, therefore, the reduction to a vacuum, which amounts to 10·36 vibrations when $P = 30$ and $T = 45°$, vary as the density of the medium, it will in all cases be

$$\frac{p - \cdot375f}{30} \times \frac{45 + 448}{t + 448} \times 10\cdot36 = \frac{16p - 6f}{t + 448} \times 10\cdot64.$$

Hence, when $p = 30$ inches and $t = 80°$, the reduction will be diminished about an eightieth part by the presence of aqueous vapour in a state of saturation, for then $f = 1$ inch. However, from the circumstance that hydrogen, compared with air, requires a greater reduction than in the ratio of the density, something of the sort may in a slight degree belong to aqueous vapour. It is farther to be observed, that the constant factor of the above correction applies to the invariable pendulum used by Major Sabine; and that almost every pendulum of a different form or construction will require a different number. A table of these is given on next page.

That part of the difference between the old and new corrections which is occasioned by barometric variations, must be extremely small in all cases of comparison between stations which differ little in their heights above the level of the sea. The specific gravity of an invariable brass pendulum being about 8·4, an inch in the barometer will correspond in buoyancy to about 0·21 of a vibration a day, which, multiplied by 0·65, is about 0·14 vibration. In the comparison of tropical and extratropical stations, the barometer, in the middle and high latitudes, is liable to fluctuate an inch and more from the mean height, which is uniform, or nearly so, within the tropics; but as the observations generally include several days at each station, and as, in proportion to their continuance, the barometer will approximate to its mean height, it will be found that a difference of half an inch in the barometric height at two stations is a rare occurrence. The correction for this is not more than 0·07 of a vibration to be added to the daily number at the station where the barometer was highest. The liability to error from variations of temperature at different stations is, however, far more considerable than from variations of pressure; sufficiently so, indeed, to become in some cases influential on the ellipticity deduced. A difference of 40° of Fahrenheit between the temperatures in the tropics and the high latitudes is by no means unfrequent; and as 16° Fahrenheit are nearly equivalent in their influence on the density of the air to one inch of the barometer, the error in such a case may amount to $0\cdot52 \times 0\cdot65 = 0\cdot34$ of a vibration per day. Moreover, as the difference of temperature is always in favour of the tropical stations, the error will be of a constant nature, unlike the greater part of the small irregularities to which pendulum experiments are liable, and which may compensate themselves by the multiplication of the experiments.

The correction for the expansion or contraction of an invariable pendulum is sometimes derived from pyrometric experiments; but as these are apt to give rather uncertain results, it is more accurate to ascertain, by direct experiments, the difference in the number of vibrations which the pendulum makes in extreme temperatures. This was the method followed by Major Sabine, who found the correction for a brass pendulum to be about 0·44 of a vibration per day for each degree of Fahrenheit; but this depends on the particular materials of which the pendulum is formed.

The experiments of Captain Kater were made, as is well known, in the free air, and its influence in retarding the vibrations, and thereby interfering with the effect of gravity, was only computed and allowed for on the old principle then generally received, but now known to be erroneous. To clear up this point, Major Sabine, at Captain Kater's request, undertook to ascertain, by direct experiment, with the apparatus above described, the actual acceleration which his pendulum would exhibit in a vacuum; and especially to determine what influence the wooden tail-pieces might have had on the original results. For, in the account of Captain Kater's experiments, it is recorded, that on the air suddenly becoming drier, the number of vibrations, which had previously been the same in both positions of the pendulum, ceased to be so; an effect which he attributed to the wooden tail-pieces losing weight by becoming drier. Major Sabine having removed the pendulum to the Royal Observatory, commenced by ascertaining its rate upon both knife-edges, in its original form unaltered, first in air of full pressure, and then in the vacuum apparatus nearly exhausted. The like experiments were repeated with the wooden tail-pieces reduced from their original length of seventeen inches to 6·4 inches, the moveable weights being altered to restore the equality of vibration. The wooden tail-pieces were next entirely removed, and brass ones seven inches long substituted for them, the weights being again altered to restore the convertibility. Lastly, the brass tail-pieces, together with the larger moveable weight, were entirely removed; and a part was filed from the heavy end, to enable the small slider to restore the convertibility.

The following are the results in the four different forms, and for both positions of the pendulum. With the wooden tail-pieces of their original length, and with the heavy end above, the daily acceleration over that in air having a pressure of thirty inches and temperature 49°, was 16·1 vibrations; and with the heavy end below, 15·7 vibrations. With wooden tail-pieces of 6·4 inches, and heavy end above, at 53°·5, the acceleration was 14·9 vibrations; below, 12·4. With brass tail-pieces, and heavy end above, at 60°, it was 12·8; below, 11·8. Lastly, without any tail-pieces, and heavy end above, at 57°·4, it was 13·7; below, 12·1. But in all of these the actual difference of pressure having been rather less than thirty inches, an allowance was made for it by simple proportion. The details are given at great length in the Philosophical Transactions for 1829 and 1831.

Major Sabine considers it a fortunate circumstance that Captain Kater had used the wooden tail-pieces just of the very sort and size as they happened to be in his original experiments, as by that means his pendulum in its original state was almost as nearly convertible in vacuo as in air. But in making this remark, Major Sabine seems to have forgotten what he had just before mentioned regarding the great effect which a change of dryness was found to have in deranging the convertibility. For if, as there is every reason to believe, the wood became much drier in vacuo from evaporating its moisture, we should be very apt to doubt the accuracy of any experiments upon, or of any comparison between, the rates of the pendulum in air and in vacuo, while so changeable a material as wood entered into its composition.

experi
ments.

Mr Baily being also desirous of ascertaining, by a more direct process than that of M. Bessel, the true value of the correction for the numerous and various pendulums in his possession, and considering the subject to be otherwise of importance to science, resolved to devote some time to examine it more minutely, and for this purpose had a vacuum apparatus fitted up, but which is of a much simpler construction than that erected in the Royal Observatory at Greenwich, as already described. It consists of a brass cylindrical tube about five feet long and six and a half inches in diameter, rounded at the bottom, and soldered at the top to a thick iron frame, on which the agate planes rest. But the confined dimensions of this tube proved a serious inconvenience, as it could not admit Kater's and some other pendulums. The iron frame is firmly screwed and fastened to solid mahogany beams fixed to the walls in the corner of a room remarkable for its uniform temperature. The upper surface of this iron frame is ground perfectly plain, and is surmounted with a moveable bell-glass. The brass tube has two small glazed openings or windows, cut in opposite sides, for the purpose of observing the arc of vibration, and the coincidences with the pendulum of the clock, which is placed behind. The lower part of the tube is secured also by cross beams, to prevent any lateral motion. In other respects this apparatus is not materially different from that in the Royal Observatory.

The following table is a summary of the results of only a part of the experiments which Mr Baily made with this apparatus. It exhibits a comparative view of the old and new corrections for the reduction to a vacuum, together with the factor n for reducing the old to the new; as also the weight of adhesive air, or that dragged by the pendulum. The difference of pressure, we suppose, is meant to be thirty inches, and the temperature 32°. The mean of Major Sabine's, in the table on page 205, was 45°.

There are several things in the table which will require some farther explanation to make them quite intelligible.

No. 1 is similar to Borda's pendulum, which is particularly described in the preceding article. Nos. 2, 3, 4 were also suspended as Borda's, and so were Nos. 5, 6, 7. Nos. 8, 9 are the same as 5, 7, but they were merely suspended by a fine wire, which was slightly held aside by the round surface of a steel wire one-fifteenth inch in diameter, a contrivance of M. Bessel, the relation of which to any practical application of the pendulum we cannot pretend to see. No. 10 is a brass cylinder with its axis vertical, and suspended by a fine wire and knife-edge. No. 11 is the same, with its axis across the plane of motion, but suspended by a knife-edge and brass rod. No. 12 is the same as the last, but with flat ends across the plane of motion. No. 13 the same, with flat ends horizontal. No. 14 is a brass tube 2·06 inches diameter and four inches long, filled with lead. It was suspended with its axis vertical by a fine wire and knife-edge. Nos. 15, 16, 17, 18, 19 are the same tube empty. No. 20 has a flat circumference about a quarter of an inch wide. It is suspended horizontally by a knife-edge and wire. No. 21 has a similar suspension. No. 22 is Kater's invariable pendulum, with which Major Sabine made the experiments described on page 205. It has a brass tail-piece about sixteen and a half inches long, for which there was not room in Mr Baily's apparatus; so that the results are those of Major Sabine, and so are the results with Nos. 23 and 24. But Major Sabine having removed the tail-pieces altogether, found the value of $n = 1{\cdot}875$ for knife-edge A, or with the heavy end below, and $= 2{\cdot}135$ for knife-edge B, or with heavy end above. Mr Baily, it is true, has slightly altered Major Sabine's numbers, by assuming a different specific gravity for the pendulum, and also for the air at a different temperature. Nos. 25, 26 are the results on the knife-edges A and B of a convertible pendulum formed of a plain brass bar 62·2 inches long. Nos. 27, 28 are those of a copper bar 62·5 inches long; and Nos. 29, 30 those of an iron bar 62·1 inches long.

The last two pendulums were taken out by the late Captain Foster, in his scientific expedition to the south, which we shall notice farther on. Nos. 31, 32, 33, 34, are the results with the four knife-edges, named A, B, C, D, of a doubly-convertible pendulum, described by Mr Baily in the Philosophical Magazine for February 1829, along with the account of some experiments which differ to an extent for which he acknowledges himself unable to give any satisfactory reason, unless it be owing to irregularities in the knife-edges and planes. It consists of a plain brass rod sixty-two inches long, without any moveable weights or sliding-pieces, and has its knife-edges convertible in pairs taken alternately; thus forming, in effect, two convertible pendulums. The distance between the knife-edges A and C was 39·3038 inches, and the number of synchronous vibrations 86218·3. The distance between B and D was 39·3084 inches, and made 86204·6 vibrations. Consequently, from these data, the lengths of the seconds pendulum will be respectively

$$\left(\frac{86218{\cdot}3}{86400}\right)^2 \times 39{\cdot}3038 = 39{\cdot}1386,$$

$$\left(\frac{86204{\cdot}6}{86400}\right)^2 \times 39{\cdot}3084 = 39{\cdot}1307.$$

The first agrees nearly with that of Captain Kater; but it is not easy to account for the discrepancy between these two results. Mr Baily does not inform us whether he had ascertained that this pendulum was perfectly free from magnetic influence, which is far from being always the case with articles of brass or copper. Nos. 35, 36, 37, 38 are the results with the four planes named A, C, *a*, *c*, which are used in place of knife-edges on a doubly-convertible pendulum formed of seven different brass tubes drawn closely one within the other, their joint thickness being 0·13 inch. The diameter of the outside is 1·5 inch, the ends are open, and the length is fifty-six inches. This pendulum is of a very singular construction; for, instead of being fitted up with steel knife-edges vibrating on agate planes, it is furnished with circular steel planes, which vibrate on a pair of fixed agate knife-edges, which are common to all the planes. The mode of suspension, therefore, is in this case reversed. The planes A and *a* are convertible, and so are C and *c*; the length between each of these pairs is very nearly a standard yard. We should, however, consider this to be rather a vague kind of pendulum, because the axis of suspension is so indeterminate that it is not restricted to such straight lines in the surface of the plane as pass through the axis of the tubes, and therefore the results must be rather indeterminate.[1] No. 39 does not materially differ from the mercurial pendulum described farther on. No. 40 is a pendulum with a spring suspension, and deal-rod three eighths of an inch in diameter, the lower part of which is encased by a leaden tube 13·5 inches long and 1·8 inch in diameter. This tube serves as the bob, and is also meant to act, by its upward expansion, as a compensation for temperature. No. 41 only differs from the preceding in having a flat deal-rod one inch broad and 0·14 inch thick, which was bevilled to a thin edge, and moved edgewise. The factor *n*, it will be seen, is greater with the flat than with the round rod. This was also found to be the case when rods of the same form as the wooden ones, but of other materials, were substituted for them.

The preceding table does not contain the half of Mr Baily's experiments. The results generally accord pretty well with the theory that a quantity of air adheres to every pendulum when in motion, and, by thus forming a portion of the moving body, diminishes its specific gravity, or rather adds to its inertia. This adhesive air seems to be confined chiefly to the two opposite portions of the pendulum which lie in the line of its motion, and very little of it adheres to or is dragged by the sides of the moving body. The shape of this coating of air will consequently partake in some measure of the form of the pendulum, subject probably to some slight modifications, of the nature of which nothing is yet known. The quantity of air dragged by the pendulum seems to depend on the extent and form of surface opposed to its action, and is not affected by the density of the body. In the case of a sphere one inch in diameter suspended by a fine wire, the weight of air dragged by the sphere alone appears to be about 0·123 grain; and for different spheres it is nearly as the cubes of their diameters. The weight of air dragged by the wire of the length of the seconds pendulum may amount to, but probably does not exceed, 0·1 grain, and perhaps is nearly the same for all fine wires of that length; so that with spheres less than an inch in diameter the weight of air dragged by the wire is nearly the same as that dragged by the sphere.

With respect to cylinders suspended by rods and swung with their flat sides opposed to the line of motion, the law of the variation is not so manifest, owing to the precise effect of the edge of the cylinder being as yet unknown. Neither are there yet sufficient data to develope the effect of the air on cylinders suspended by rods or wires, and swung with their flat sides in a horizontal position, similar to the pendulums Nos. 10 and 14. In these cases the cylinder four inches long drags much more than double the quantity of air adhering to the cylinder of two inches, although they have precisely the same diameter. With respect to very thin cylinders or discs swung with their flat sides opposed to the line of motion, the weight of air dragged by a disc of one inch in diameter appears to be about 0·149 grain, and for different discs is nearly in the ratio of the cube of the diameter; whence it appears that a thin disc drags more air than a sphere of the same diameter.

---

[1] In the Philosophical Transactions for 1830, p. 207, Mr Lubbock professes to prove, that if the knife-edge is rounded or cylindrical, the distance between the planes is still the length of the equivalent simple pendulum. But in this he has deceived himself, and only proved the converse of the proposition; for it is easily shown (as we have done farther on in the precisely similar case of Laplace's theorem), that whenever the centre of gravity is within a certain distance of the middle between the planes, their distance is greater than the length of the equivalent simple pendulum. Besides, Mr Lubbock entirely overlooks the uncertainty in the position of the axis of suspension.

The last column of the table contains the weight of air which is supposed to adhere to and be dragged by the pendulum, in consequence of the air put in motion thereby, when vibrating in the mean state of the atmosphere; or rather the quantity of air which, if applied to the *centre of gyration* of the pendulum, would produce the retardation shown by the experiment. This view of the subject was suggested by Professor Airy, the present distinguished astronomer royal, who also gives the following investigation and formula for computing the weight of adhesive air. Let N denote the number of vibrations made by a pendulum in a mean solar day, when swung in air; and let ν be the additional number which it makes when swung in vacuo. Also, let ω be the weight of the pendulum in grains troy, S its vibrating specific gravity, and σ the specific gravity of the air. Now, since the force of gravity diminishes in the ratio of $(N+\nu)^2$ to N^2, or in the ratio nearly of $\left(1+\frac{2\nu}{N}\right)$ to 1, it follows, that when the pendulum vibrates in air, it is as if, retaining the inertia of its weight ω, it had the gravity of only $\omega \times \frac{N^2}{(N+\nu)^2} = \omega\left(1-\frac{2\nu}{N}\right)$ nearly; or as if it had lost the weight $\omega \times \frac{2\nu}{N}$. But the weight which it has really lost from the displacement of a quantity of air is $\omega \times \frac{\sigma}{S}$. Consequently, the portion which is not accounted for by the mere displacement of the air is $\omega\left(\frac{2\nu}{N}-\frac{\sigma}{S}\right)$, and which may be considered as the additional weight gained by the pendulum (or rather the addition to its inertia) when moving in air supposed to be *applied to the centre of gyration*. The inertia of the whole pendulum in resisting angular motion is the same as if it were collected at the *centre of gyration*. The immediate result of the experiment and formula above given is, that the inertia of the whole pendulum ought to be increased in the proportion of $\left(1+\frac{2\nu}{N}-\frac{\sigma}{S}\right)$ to 1; or that, instead of supposing the inertia ω to be applied at the centre of gyration, the inertia $\omega\left(1+\frac{2\nu}{N}-\frac{\sigma}{S}\right)$ ought to be applied there. The addition to the inertia is therefore $\omega\left(\frac{2\nu}{N}-\frac{\sigma}{S}\right)$ applied where that of the whole pendulum may be supposed to be applied, that is, at the centre of gyration.

As already mentioned, Major Sabine has alleged, that the usual formula for the reduction of the vibrations of a pendulum to indefinitely small arcs is erroneous, as it does not agree with the result of a series of experiments which he had undertaken for the purpose of testing it, and which, in the case of the convertible pendulum tried by him, would require the hitherto assumed corrections to be multiplied by 1·13 when the great weight is below, and by 1·4 when above. As this was somewhat at variance with Mr Baily's view of the matter, he determined on making a few trials, in order to ascertain more minutely, by experiment, the difference which really arises from the use of larger and smaller arcs; and for this purpose he took a brass bar convertible pendulum, placing it in the vacuum apparatus, under about one inch pressure of the atmosphere. Two series were made on the knife-edge which was nearest the end of the bar, and which he calls A, and two on the other, named B; and each of these series was divided into three portions, in the first of which the width of the arc was taken from about 1° to 0°·6, in the second from 0°·6 to 0°·38, and in the third from 0°·38 to 0°·2 and 0°·1. The first series on the knife-edge A required the usual correction to be increased about a tenth, which agrees nearly with Major Sabine's experiments; but the second series on the same knife-edge required the correction to be diminished nearly as much. Mr Baily, therefore, considers these two series as neutralizing each other, and that the difference observed must lie within the errors of observation. On the knife-edge B, both series required the correction to be increased one fifth, which is only half the amount indicated by Major Sabine's experiments. Further inquiries, therefore, are necessary to clear up this point;[1] not only as to the cause of the anomaly, whether it arises, as Major Sabine supposes, from a sliding of the knife-edges on the agate planes, in which case it may differ in different pendulums, but also as to the accuracy of the generally received formula, which several mathematicians allege to become inaccurate when the arc is very large. But whether the difference really arises from a defect in the formula, or from a sliding of the knife-edges, or from the variable effect of the air on the pendulum, or from all three, remains still to be decided. Perhaps magnetism is not always sufficiently guarded against. There are instances of articles of brass having become highly magnetic from the manner in which they have been worked; so much so, indeed, in parts of chronometers, as not only to derange their performance, but even to arrest their motions altogether. According to M. Bessel, the knife-edges slide on the planes. The sliding is proportional to the extent of the arc of vibration, and is always in the direction in which the pendulum is moving. Now, if the sliding can really be so well observed and appreciated, it must be very considerable; probably far exceeding the sliding and friction of a fine cylindric surface turning, or rather sliding round, in a nicely jewelled groove.

Defects of the knife-edges and planes.

It has been shown by Major Sabine in his work on the figure of the earth, page 195, that in a pendulum with knife-edges, a considerable difference may arise in the results, if they be used with different planes; but it does not seem to have occurred to any one versed in these experiments, till discovered by Mr Baily, that a much greater difference than that just referred to may arise while using the *same* knife-edge with the *same* plane. This fact had probably long escaped detection, from the peculiar manner in which pendulum experiments are usually conducted; for, on examining the detail of most of them, it will be found that, after the pendulum, at any one station, has been placed in its Y's, it has never been removed from them, but merely raised and lowered again as occasion may require, till it has been ultimately dismounted and packed up for another station. In this way any inconsistency that might otherwise have occurred is avoided, and consequently escapes detection. Mr Baily considers the pendulum furnished with a knife-edge and agate planes, as at present constructed, to be a very inadequate instrument for the delicate purposes for which it was originally intended; and that a more rigid examination and adjustment of those parts of the instrument are requisite, before we can depend on it, either for the determination of the length of the seconds pendulum, or even for the comparison of results obtained in different parts of the world. The knife-edge is seldom or never perfectly straight; the planes, whether from being carelessly ground, or being so thin as to be flexible, are seldom or never perfectly true; so that as there is generally a little play in the Y's, the knife-edge is not always let down on the same parts of the agate plane. This may be detected by holding a candle behind the knife-edge while it is resting on the plane; for, by means of its rays, the smallest inequalities in the points of contact are readily discernible. But the fact is rendered still more evident, by reversing the ends of the same knife-edge in the Y's, when a sensible difference in the result generally takes place. Among the numerous pendulums in Mr Baily's possession, he has only met with one whose results were not altered by an appreciable quantity when the knife-edge is reversed in the Y's, or turned half round in azimuth. If the knife-edge and plane were perfectly correct and true, there ought to be no difference in the results, whichever side of the pendulum is next the observer; whereas a difference of upwards of two vibrations in a day actually occurs in one of the pendulums above alluded to.

---

[1] Mr Baily advises, that any future experiments on this question should be made in the free air, and not, as formerly, in vacuo. We should, however, have great doubts of the correctness of this opinion; for how then could the very different effects of the air on wider and narrower vibrations be distinguished from the effects which belong to the differences of the arcs themselves?

Rolling pendulum.

The theory of pendulums suspended on rolling cylinders under various forms and circumstances, is treated at considerable length, and with such ability, by Euler, in the *Acta Petropolitana* (tom. iv. part ii. for 1780), and again in the *Nova Acta* (tom. vi. for 1788), that in place of here entering into any elaborate investigation on this head, we shall now, for brevity's sake, take advantage of Euler's results, especially in examining the merits of that celebrated theorem which the late illustrious Laplace discovered about twenty years ago, and which, when it appeared, tended greatly to allay the very considerable fears which had previously existed regarding the accuracy of the experiments with convertible pendulums. For the knife-edges on which these had been suspended were considered liable to become blunted, or in some measure changed into cylindric surfaces, by their turning, under considerable pressure, on the horizontal planes; and it had been feared that this might affect the time of vibration. The theorem, though sometimes a little differently expressed, amounts to this: when a rolling pendulum is convertible, vibrating alike fast on each of two equal and parallel cylinders rolling on a horizontal plane, the distance between the cylindric surfaces is the length of the equivalent simple pendulum.

Laplace's theorem.

Though usually regarded as universally true, this theorem fails whenever the distances of the two cylinders from the centre of gravity do not differ by a quantity which greatly exceeds a diameter of the cylinders. Fortunately, it holds good in the cases which are of most importance for the convertible pendulum; but it is not perhaps much to the credit of science that the true limits of the theorem should not have been ascertained; and probably, too, from mathematicians having so much mistaken the nature of the proposition, that the reasonings hitherto employed by them in proof of it have at best amounted to demonstrations of its converse, or rather of the converse only of its possible cases, namely, that positions may always be found for two rolling suspensions of the sort above described, such, that they shall make the pendulum convertible, and have their distance equal to the given length of an equivalent simple pendulum.

The investigation of Laplace himself, while it has the defects just noticed, is so unnecessarily intricate, that it would be tedious to discuss its merits; but in the Philosophical Transactions for 1818, p. 95, the late eminent philosopher, Dr Thomas Young, has given what he considered to be a more elementary demonstration of this theorem, though it is, in fact, of its converse; and he has again, in the Philosophical Transactions for 1819, p. 94, attempted, from some of Euler's results, to deduce the same thing, but which comes to be still its converse, as will be afterwards noticed. There is likewise an abridgement of Euler's investigations for 1788 given in the Philosophical Magazine for December 1821, and with it is coupled a similar, but not more successful, attempt at deducing the theorem in question; for in all of these the proof is applicable to nothing more than the converse of the possible cases of Laplace's theorem, though that converse itself really forms a theorem which never fails.

If a be the distance of the centre of gravity of the rolling pendulum from the centre of the upper cylinder, c the radius of each cylinder, and k the radius of gyration, with respect to an axis passing through the centre of gravity of the pendulum, and parallel to the axes of the cylinders; then it has been demonstrated by Euler, in the *Nova Acta Petropolitana* for 1788 (p. 149), that this rolling pendulum will perform a small vibration in the same time as a simple pendulum whose length is $l = \frac{k^2 + (a - c)^2}{a}$. But it is easily shown that this must vibrate in a shorter time, especially with the heavier end of the convertible pendulum uppermost, than the same pendulum would do were it suspended by knife-edges substituted for, and put exactly in the places of, the cylindric surfaces. For, supposing the pendulum to continue a convertible one, after being thus modified, we should, from the well-known relation between the centres of suspension, gravity, and oscillation, have k a mean proportional between the segments into which the centre of gravity divides l the distance between the knife-edges, or we should have $k^2 = (l - a + c)(a - c)$, and thence $l = \frac{k^2 + (a - c)^2}{a - c}$, which corresponds to a simple pendulum longer than the former in the ratio of a to $a - c$. Hence it appears, that a rolling pendulum always vibrates faster than if it were suspended by a knife-edge substituted exactly in the place of the cylindric surface; so that when the rolling pendulum is a convertible one, the cylindric surfaces always have positions different from those of two knife-edges, which, with an equal interval between them, would also render the same pendulum convertible, and preserve the same time of vibration; and, therefore, to make the two proposed knife-edges keep time with the cylinders, the former would need to be shifted so as to shorten the time of vibration, which, when possible, may be effected by bringing the more distant knife-edge nearer the centre of gravity, and removing the other as much farther off, so as still to preserve an interval $= l$ between them. In that case, putting x for the space to be so shifted, we should, for the reason above given, have $k^2 = (l - a + c - x)(a - c + x)$, and $l = \frac{k^2 + (a - c + x)^2}{a - c + x}$, which, according to the theorem, is to equal the efficient length of the rolling pendulum, namely, $\frac{k^2 + (a - c)}{a}$. Wherefore, substituting the above value for k^2 in this last formula, should afford a ready means of finding such an expression for x as shall reconcile, when possible, the times of vibration on the two different sorts of suspensions; for it then becomes

$$l = \frac{l(a - c + x) - 2(a - c)x - x^2}{a},$$

whence $x^2 - \big(l - 2(a - c)\big)x = -cl$, and $x = \frac{1}{2}l - a + c \pm \sqrt{\big((\frac{1}{2}l - a + c)^2 - cl\big)}$, where both values of x, when real, will be positive, or both negative, according as $\frac{1}{2} l$ is greater or less than $a - c$. But both become imaginary; and, consequently, Laplace's theorem fails when $(\frac{1}{2} l - a + c)^2$ is less than cl; because the rolling pendulum then vibrates unavoidably faster than the other. This is, besides, still more obvious from another consideration in the case when the centre of gravity is midway between the cylinders; for then no knife-edges embracing as great an interval can give the same time of vibration, because when the knife-edges coincide with the cylindrical surfaces, they are already too slow, and would be still more so if at unequal distances from the centre of gravity. Thus, the rolling pendulum, in that case, having only $\frac{k^2 + (a - c)^2}{a} = \frac{2\,(a - c)^2}{a}$ for its effective length, must vibrate more quickly than the other, whose effective length is $\frac{k^2 + (a - c)^2}{a - c} = 2\,(a - c)$, and exceeds the former by nearly $2c$, but would be still greater were the knife-edges at unequal distances from the centre of gravity. The defects of this celebrated theorem, therefore, increase with the diameter of the cylinders; and it also appears from Euler's investigations, that the times of vibration in the rolling pendulum are more unequal, or increase still more with the width of the arc, than they do in the circular pendulum. For in the former the time of vibration is $\frac{\pi h}{\sqrt{(2ag)}} + \frac{\pi b^2 (h^2 + 4ac)}{4h \sqrt{(2ag)}}$, and in the latter $\frac{\pi h}{\sqrt{(2ag)}} + \frac{\pi b^2 h}{4\sqrt{(2ag)}}$; where b is the sine of one fourth the arc of vibration, g the force of gravity, $\pi = 3{\cdot}1416$, and $h^2 = k^2 + (a - c)^2$; but when $c = 0$, $h^2 = k^2 + a^2$ only. The second term in each of the above expressions is the respective reduction of the times of vibration, to what they should be in indefinitely small arcs.

From the equation $l = \frac{k^2 + (a - c)^2}{a}$, Dr Young, in the Philosophical Transactions for 1819, p. 94, deduces $a = \frac{1}{2} l + c \pm \sqrt{}\ldots$ The last term he leaves blank, as of no consequence, because he supposes these two values of a to be the parts into which the centre of gravity divides the distance between the centres of the cylinders, so that when added together, the two quantities affected by the radical sign, no matter of what value, should destroy one another, leaving the remaining sum $= l + 2c$, which he thence infers to be the distance between the centres of the cylinders. But this eminent mathematician, by thus omitting the quantity affected by the radical sign, has overlooked the circumstance that it, namely, $\pm \sqrt{(\frac{1}{4} l^2 + cl - k^2)}$, never vanishes, and, consequently, that his investigation does not embrace those cases in which the distances of the cylinders from the centre of gravity do not differ by far more than one of their diameters. So that the premises of the proposition which he proves do not suppose the cylinders to have given positions, or already to have positions forming a convertible pendulum, but that two positions may always be found for them, such that their time of vibration, and the interval between them, shall be equal to those of two knife-edges with given positions. In short, the proof applies to nothing more than the converse of the possible cases of Laplace's theorem.

In order to ascertain the limits of certain errors, though of a different description from those now discussed, but which may be supposed to arise in experiments with the convertible pendulum, Mr Lubbock has, in the Philosophical Transactions for 1830, investigated the effect on the number of vibrations of a given pendulum, corresponding to given deviations in the positions of the knife-edges and planes, and finds that a small deviation of one of the knife-edges in azimuth has no sensible effect. It is otherwise with a deviation in altitude; for one degree on that position of the knife-edge produces an acceleration of three seconds in twenty-four hours. Still more considerable is the effect of a deviation from horizontality in the agate planes; for ten minutes of a degree produce a daily acceleration of six seconds. Both the two latter deviations render the distance between the knife-edges greater than the length of the equivalent simple pendulum.

During the last twenty years, a vast number of experiments have been made by means of the pendulum, on the relative force of gravity in different parts of the world, with the view of contributing towards the determination of the true figure of the earth. Accounts of these have been published in the scientific periodicals, and in separate works; but our limits will only permit us to notice briefly a few which are more particularly interesting.

Difference in pendulums at London and Paris.

The length of the seconds pendulum having been determined in London by the method and apparatus of Kater, and in Paris by those of Borda and Biot, and the standard linear measures of the two countries having been respectively referred to these pendulums for future verification, an attempt was made about twenty years ago to ascertain the difference between the actual number of vibrations which invariable pendulums conveyed between London and Paris would make at these places. A summary account of the operations is given in the *Base du Système Métrique*, tom. iii.; but, from certain accidental causes, some doubts have always attached to the result. To clear up this point by solving the question anew, Major Sabine, early in the year 1827, had two invariable pendulums conveyed to Paris, where an extensive series of experiments were made by himself, and several eminent French philosophers, in the very spot where M. Biot had determined the length of the seconds pendulum. The two pendulums were next brought back to London, and similar operations were made with them in the room of Mr Browne's house, Portland Place, where Captain Kater had originally made his experiments. The comparison of the results showed, that in the latter place the pendulums made twelve vibrations more per day than at Paris, answering to 0·01088 inch in the length. The reductions, it is true, were made according to the old rules, though it is likely that this would occasion nearly equal errors in both quantities, so as not to affect their difference. The details are given at great length in the Philosophical Transactions for 1828, and the new corrections may still be applied.

Difference in pendulums at London and Greenwich.

In order the better to insure that the various pendulum experiments which had been made in Mr Browne's house, Portland Place, London, particularly those of Captain Kater, might be rendered comparable with any similar experiments made at the Royal Observatory at Greenwich, Major Sabine, at the request of the Royal Society, undertook to settle the question by direct experiment, as detailed at great length in the Philosophical Transactions for 1829. For this purpose, he first made a series of experiments on the daily rate of an invariable pendulum in Mr Browne's house, and then did the like with the same instrument taken to Greenwich. The result was, that the pendulum made 0·52 of a vibration more per day at Greenwich than at London. The knife-edge of the pendulum was then fresh ground, and a new series of experiments made at both places, with a similar result of 0·44. The mean is 0·48 of a vibration. Now, as the latitude of the Royal Observatory is 2′ 28″ south of Mr Browne's house, and as it is about fifty feet above its level, a retardation, from these causes combined, of about 0·27 of a vibration, was to have been expected at Greenwich, instead of an acceleration. The retardation, as computed for the difference in latitude, would be 0·15 vibration; and that for fifty feet of difference in elevation, being about 0·20, would, when multiplied by Dr Young's co-efficient of 0·6, be 0·12 of a vibration. These added to 0·48, make 0·75 of a vibration; by which amount the result of actual experiment differs from what might have been anticipated by mere theory.

In the autumn of the same year, 1828, Major Sabine transported the same invariable pendulum to Altona, where he made a series of observations with it. The like was done with the same instrument again in 1829, at Greenwich. The result was, that the pendulum made 8·33 more vibrations per day at Altona than at Greenwich.

Captain Foster's experiments.

The late lamented Captain Henry Foster, who had been sent out on a scientific expedition towards the south, the principal object of which was to swing the pendulum near the equator, and also at various places in the southern hemisphere, took out with him four pendulums, two of which were of the kind called Kater's invariable pendulum, but the other two were of a new construction, recommended by Mr Baily, the one of iron and the other of copper, each of which was furnished with two knife-edges; so that, in effect, Captain Foster might be considered as having taken out six different and independent pendulums. These were swung at fourteen different places, and, with the exception of the experiments with one of the brass pendulums at South Shetland, the results are very accordant, and show that the pendulum, even with its present imperfections, affords an accurate measure of the relative force of gravity at different places. But the sources of minute errors more recently detected in this instrument will render future experiments more valuable and comparable with each other. As our limits will not admit of entering into a comparative examination of the results obtained at each place, it must suffice here to state the general result at the several stations, referring, for the whole details, to the Memoirs of the Astronomical Society, vol. vii. For the purpose of deducing these results with the least chance of error, Mr Baily has adopted the usual method of minimum squares, whereby he finds that if v be the number of vibrations at the equator, f the co-efficient of the increase of the force of gravity, L the latitude of any other place where the same pendulum makes V vibrations, the general formula $V = v(1 + f \sin.^2 L)^{\frac{1}{2}}$ becomes, in the present case, and according to Captain Foster's experiments,

$$V = (7441507482 + 38666418 \sin.^2 L)^{\frac{1}{2}}.$$

The following table shows the observed mean results of all the pendulums, deduced from the whole of the experiments, at each station, as well as the value computed from the above formula, together with the error or difference thence arising.

The last column clearly indicates that the pendulum is powerfully affected by local circumstances, since the difference between the observed and computed results in most of the cases far exceeds the probable errors of observation, and all the pendulums agree in their indication of the degree of intensity at the several places. This fact, however, is rendered more striking by combining the experiments hitherto made with the invariable pendulum by the several English, French, and Russian voyagers. In this manner Mr Baily has obtained fifty-one different places where the pendulum has been swung; and at several of these stations this has been done by more than one experimentalist. The results, therefore, being in several instances confirmed either by the experiments of various persons, or by various pendulums swung by the same person, show most decidedly that there is some local influence on the pendulum at such stations, with the exact nature of which we are unacquainted, and which baffles all our efforts to deduce the true figure of the earth from pendulum experiments made at a *few* places only; for the results deduced from such experiments will vary according to the selection which is made of the stations. And it is a remarkable circumstance, that the force of gravity seems to be greater in islands remote from the mainland, such as St Helena, Ascension, &c. than it is on continents.

The ellipticity of the earth, deduced from Captain Foster's experiments, is $\frac{1}{289{\cdot}48}$; Major Sabine made it $\frac{1}{288{\cdot}40}$; the mean of the French and Russian experiments is $\frac{1}{267{\cdot}23}$; the mean of the whole combined, $\frac{1}{285{\cdot}26}$. The total number of coincidences made by Captain Foster was more than 20,000, and occupied upwards of 3180 hours. The total time occupied by Major Sabine was only 598 hours; that by Captain Freycinet only 367 hours; and that by Captain Duperrey only 256 hours. So that Captain Foster's experiments are five times more extensive than Major Sabine's, and fully twice and a half more extensive than those of all the above experimentalists united. They have also the advantage of having been made with a greater variety of pendulums, and cannot fail to be duly appreciated in all inquiries connected with that important subject which they were intended to elucidate, the true figure of the earth.

Among the various sources of discordance between the results of different experimenters, a fertile one seems to be the very different reductions which they use for the expansion of the air, or for reducing its density from one temperature to another. Thus, although few things in natural philosophy are better determined than the expansion of the air, almost every one uses his own favourite reduction for it. According to the experiments of Dalton, Gay-Lussac, &c., the expansion of air for one degree of Fahrenheit, and whether dry or moist, is equal to the $(t + 448)$th part of its bulk, under a constant pressure, at the temperature t. From the circumstance of this being the 480th part of the bulk at 32°, and from 32° being often used as a standard temperature, seems to have arisen the common-place phrase, that "*the expansion of air for one degree is the 480th part,*" a phrase which is always more or less erroneous, unless it mean the bulk at 32°; for it is the 448th of the bulk at the zero of Fahrenheit, the 528th of it at 80°, and the 660th of the bulk at 212°, &c. This, though an extremely simple affair, seems much too abstruse for the greater part of writers on chemistry, and for not a few on natural philosophy, among whom we find the above phrase means the 480th part of the bulk at any temperature whatever. The error is precisely of the same sort as if, because a shilling is the 480th part of twenty-four pounds, it should be reckoned the 480th part of every other sum. The greatest dunces rarely do any thing like this in the ordinary affairs of life; and why should such blunders pervade writings which profess to be scientific?

In 1830, Major Sabine having entirely removed the tail-pieces and the larger moveable weight from Captain Kater's convertible pendulum, executed a very extensive series of experiments with it at the Royal Observatory, Greenwich, for the purpose of accurately determining the length of the seconds pendulum there; and the result was, that at the temperature of 62°, and in a vacuum, it is 39·13734 inches. But notwithstanding the very great care which seems to have been bestowed on these experiments, doubts regarding their accuracy have been started by Mr Baily, particularly on account of an anomaly which occurs on the face of the observations. For it appears, that when the small sliding weight was shifted about 0·133 inch, it caused a daily acceleration of 0·10 vibration on the knife-edge A, or with the heavy end below; whilst it caused a retardation of 1·12 vibration on the knife-edge B. Now this is quite contrary to the known principles of the pendulum, since the effect of a slider of this sort is to produce an alteration of the same kind in each knife-edge, differing only in degree.

We suspect that with convertible pendulums sufficient care is not always taken to insure that the centre of gravity and both knife-edges shall be accurately in the same plane; without this the results must be very doubtful.

V.—ATTACHED PENDULUMS.

Thus far we have treated principally of what relates to detached pendulums, and of the corrections to be computed and applied to the numerical results. What follows more especially belongs to clock pendulums, and to the contrivances which enable them to correct or compensate themselves for the effects of atmospherical pressure, temperature, &c.

On examining the new correction for the mercurial pendulum, which is the one now generally employed in clocks for astronomical purposes, though, for reasons given farther on, we do not consider it as affording by any means the best compensation for temperature, it will be found that a difference of one inch in the pressure of the atmosphere should alter the daily rate of the clock by 0·414 second, which is more than double the quantity hitherto assumed as depending on the change of the barometer, and which therefore should no longer be disregarded by the astronomer. To obviate this defect in the clock at the Observatory at Armagh, Dr Robinson has attached two syphon-barometers to the mercurial pendulum, one on each side of the rod, and so placed that the variations in the height of the mercury in their tubes may exactly compensate the effect of a change of atmospheric pressure.[1] In the Quarterly Journal of Science (vol. xv.) Mr Davies Gilbert has endeavoured to show how a compensation for the effects of pressure may be produced, by making the arc of vibration just of such an extent that the effect produced by the difference of density in the atmosphere may be exactly counterbalanced by the effect arising from the difference in the arc of vibration caused by such difference of density. But by proceeding agreeably to the formula which Mr Gilbert has there given for finding the value of such arc, and on the assumption of the accuracy of the new correction above mentioned, Mr Baily finds that the required arc of semi-vibration should be 2° 45′, whereas in astronomical clocks it seldom exceeds 2°, which would produce only half the requisite compensation; so that, after following up Mr Gilbert's theory, there still remains a part of the effect, exceeding 0·2 second, on the daily rate of the mercurial pendulum, as produced by a difference of one inch of pressure. Did the extent of the arc depend on no other variable cause than the density of the air, we should think that an increase in the bulk of the pendulum would readily give the requisite addition to the compensation. For, from Mr Baily's experiments, it appears that the retardation of the air depends principally on the bulk of the pendulum, though it seems to be affected by other circumstances at present not well understood. But since the extent of the arc of vibration depends very much on the variable state of the oil, and the degree of cleanness of the clock, neither of which keeps pace with the density of the air, it seems greatly preferable to have recourse to barometers like those of Dr Robinson, and to employ a spring of suspension, having its length, if possible, so adjusted as to equalize the times of vibration in the wider and narrower arcs, which is more particularly considered farther on.

Compensation for temperature.

All bodies expand by heat and contract by cold in a greater or less degree; and consequently every attempt to discover any simple pendulum-rod, whether natural or artificial, which could continue of an invariable length, so as to have its rate of motion independent of variations of temperature, has uniformly failed. To obviate this inconvenience, a variety of devices have been resorted to by ingenious persons, and some of them with success. About the year 1715, the celebrated artist Mr George Graham attempted, by means of the very imperfect pyrometers then in use, to ascertain the relative expansions of several metals, in the expectation that the difference in some two or more of them, when applied to act in opposite directions, would enable him to construct a compound rod of an invariable length. But, owing to the defects of his pyrometer, the difference between their expansions seemed so inconsiderable, that he then relinquished all hope of effecting a compensation in this way. Some time after, it occurred to him that the great expansibility of mercury might be rendered available for this purpose; and, accordingly, in 1721 he had succeeded so far in the construction of the following kind of pendulum, that the usual error in the extremes of temperature was reduced to one eighth, as is described at length in the Philosophical Transactions for 1726.

Mercurial pendulum.

The bob or weight of the mercurial pendulum, represented in fig. 3, Plate CCCCIII., consists of a cylindrical glass jar A, containing mercury. The rod BB is of steel, and single till it reaches down thirty-two inches from the suspension, or within ten inches of the bottom, where it screws into the milled-headed nut D, in the middle of the cross bar EE of the stirrup FF, which carries the glass jar resting on the circular base G. This base, shown separately in fig. 4, is of brass, slightly hollowed to fit the jar, and a cover precisely similar to it is used on the top of the jar. Besides this, Mr Browne, with the view of keeping the surface of the mercury perfectly flat, covers it with a float of plate-glass. The jar is generally about two inches wide and eight deep, having about 6·8 inches of this depth filled with mercury; but the quantity of mercury depends very much on the weight and expansibility of the other materials. If, upon trial, the clock go too slow with an increase of temperature, showing the downward expansion of the rods to be too great for the upward expansion of the mercury, more of this fluid must be poured into the jar; if the reverse take place, some mercury must be withdrawn. In this manner may the expansion and contraction of the mercury be made exactly to compensate those of the other materials, so as to preserve invariable the distance of the centre of oscillation from the axis or other suspension. This pendulum, though in great repute, is by no means free from objection; for, since there is often a sensible difference of temperature in a small difference of height, the mercury, being much lower down than the greater part of the rod, is liable to have a somewhat different temperature, and consequently to fail in producing at all times an exact compensation. It is also alleged, that such a great mass of mercury, being enclosed in so bad a conductor as glass, does not acquire the changes of temperature so promptly as the metallic rods. To obviate this last, glass is sometimes dispensed with, and an iron cylinder, or one of brass, varnished inside to prevent the action of the mercury, is substituted for the glass. On the other hand, Captain Kater had a cylinder and rod blown all in one piece of glass, similar to a bottle with a very long neck. He had no other rod or frame. A cap of brass was clamped by screws to the top of the glass rod, and to this was pinned the suspension spring. Pendulums of this sort are said to have been at one time used in France. They are much less expensive than those with the metal rods, &c.

---

[1] See Memoirs of the Astronomical Society, vol. v.

In the Philosophical Magazine for August 1819, Dr Firminger has given a description of a mercurial pendulum, with the dimensions of all the parts, apparently to a great degree of exactness, as computed by Mr Gavin Lowe for the Royal Observatory, and which have, therefore, been often copied and referred to as of standard authority. But, on examination, they will be found to be very incorrect; for, in computing the position of the centre of oscillation, and even by means of an algebraic formula, no regard is had to any dimensions of the materials but their lengths. Thus, neither the diameter of the cylinder, nor the still greater breadth of the frame or stirrup, is taken into account, although both have a considerable influence on the result.

Troughton's mercurial pendulum.

The late ingenious Mr Troughton contrived a method of constructing a compensating pendulum with much less mercury than is usually employed. Instead of the cylindrical cistern, he put the mercury into a bulb and tube in the form of a large thermometer. In that case, forty-five ounces of mercury sufficed for the compensation, but he also used an ordinary bob. According to Dr Pearson, it is a property of this contrivance, that if the column of mercury be made to reach either above or not quite up to the middle of the pendulum, at a mean temperature, the compensation will be in defect; but when the column reaches exactly to the middle, at a mean temperature, the compensation is exact. But in this there must be some mistake; for nothing can be more evident than that the column may reach exactly to the middle, while the sizes of the bulb and tube may be such as to produce nothing at all approaching to a correct compensation.

Ward's pendulum.

Ward's pendulum is a more recent one than the gridiron pendulum; but being essentially the same, and simpler in a very great degree, the description of it will form an easy introduction to that of the other. It is shown in fig. 5, Plate CCCCIII., where *aa* and *bb* are two flat rods of iron or steel, about half an inch broad and an eighth thick. Between these is a third rod *cc* of zinc, nearly the same in breadth, and a quarter of an inch thick. The one steel rod *aa* is cranked at the upper end, and the other *bb*, at the lower end, for the purpose of bringing the suspension spring and the centre of the bob to be in the same vertical line with the zinc rod. These three rods are held together by the screws *d*, *d*, *d*, *d*, but only so as still to allow them to shift with ease upon each other in a slight degree. These screws, passing through oblong holes in the rods *aa* and *cc*, screw into the rod *bb*, while the rod *aa* is held firmly to the zinc one *cc* by the single screw *e*, which, therefore, forms in effect the lower limit of the zinc rod; but since the proper length of the zinc rod can almost never be hit on at first, several holes are provided for the screw *e*, in order that on trial it may be put into the one which gives the true compensation. The steel rod *bb*, which carries the bob of the pendulum, is knee'd, so as to hook against the upper end of the zinc rod; and the other steel rod *aa* might in like manner, without the screw *e*, have hooked against the lower end of the zinc, but in that case it would not have been so easy to adjust the proper length of the zinc. The expansion of zinc exceeds that of steel in the ratio of 2·7 to one nearly. In some pendulums the zinc rod is about twenty-five inches long, in others fully twenty-seven. It is obvious, that as the two rods of steel *aa*, *bb* expand downward, lengthening the pendulum, the zinc rod *cc* expands upward, drawing up the bob by means of the steel rod *bb*, so as to raise, or rather preserve the proper position of the centre of oscillation. It is necessary that the expansion of the zinc rod should more than compensate an equal length of each of the steel rods, because they stretch beyond it both ways. But the bob itself, by expanding upward from the nut on which it rests beneath, will a little aid the compensation.

The gridiron pendulum, the invention of the celebrated John Harrison, is represented in fig. 6, Plate CCCCIII., and ordinarily consists of five rods of steel and four of brass, placed in alternate order, the former being shaded darker for distinction; but since eight of these act in pairs for the sake of steadiness, there are in effect only three rods of steel and two of brass. Their mode of action will be readily understood by tracing the expansion of the rods in the order of their connection; 1*st*, tracing down from the cross bar attached to the suspension, the two outer rods of steel, which expand downward, and act together as one rod only; 2*d*, tracing up the two brass rods next on the inside of these, which expand upward, and likewise act together; 3*d*, down the two steel rods inside of the last, which expand downward; 4*th*, up the two rods of brass next inside of these, which expand upward; and, *lastly*, down the middle rod of steel, which carries the bob, and expands downward. None of the cross pieces have any hold of the middle rod except the very short one at its upper end. The other cross pieces at some distance from the ends are double, two being on each side of the rods; but they are only fixed to the two outer rods to keep the whole system more evenly. In this arrangement, the expansion of all the steel rods is downward, and that of all the brass upward. It is necessary that the expansion of the latter metal should be much the greater, in order to compensate for there being one rod more of steel than of brass, and for the parts of steel which reach above and below the brass. But the precise compensation required is so uncertain, that the length of the rods can only be previously estimated approximately, and must afterwards be adjusted by trial if necessary. This, when well executed, is a more perfect compensation than the mercurial pendulum; because the average temperatures of the parts whose expansions are opposed to each other must be almost exactly the same. The number, order, length, and thickness of the bars often differ considerably from the above. Thus, it is evident that the whole gridiron part now described might be inverted without altering the effect. Sometimes the gridiron consists of a numerous assemblage of very short rods at the lower end of the pendulum, where they are liable to have a different temperature from that of the principal rod, which they are meant to compensate, and which has its greater part far above them. Berthoud would have liked to have deprived Harrison of the honour of inventing the gridiron pendulum, because he did not publish an account of it till 1767. But it was known to the public almost from the time it was made in 1726; and Short has described it in the Philosophical Transactions for 1751.

Graham had proposed to increase the effect of the difference between the expansions of two metals by means of levers. This was put in practice by Ellicot in a pendulum described by him in the Philosophical Transactions for 1751. Many other pendulums have been made on this principle; but, unless great care be taken to avoid friction, they are liable either not to act at all, or to move by starts in a very uncertain manner.

Some pendulums are partly composed of tubes, and these generally differ only in form from those of the gridiron construction. The following is perhaps amongst the best, as well as the simplest, of the tubular sort in use. A rod of steel attached to and descending from the suspension is covered by a tube of zinc, which rests on a shoulder or nut on the bottom of the rod; over this again is put a tube of iron or steel, having a contraction or flat ring at its upper end, to rest or hang upon the top of the zinc; and this outer tube carries at its lower end the bob or weight. This pendulum needs no farther description, being essentially the same as that of Ward, only the parts are not so equally exposed to changes of temperature. Sometimes lead is used in place of zinc, and rods of steel instead of the outer tube.

Smeaton's pendulum has a solid glass rod, covered to the extent of a foot by a tube of zinc, which rests on a nut or shoulder at the bottom of the rod, and expands upward. This is covered by a tube of iron also a foot long, hooking upon the top of the zinc, and expanding downward. The iron again has a shoulder at the bottom, on which rests a massy tube of lead incasing the other two, and expanding upward. These three tubes therefore form both the bob and the compensation. This construction is neither difficult nor expensive, but the parts whose expansions are opposed to each other are, like those of some of the pendulums already described, liable to be of somewhat different temperatures.

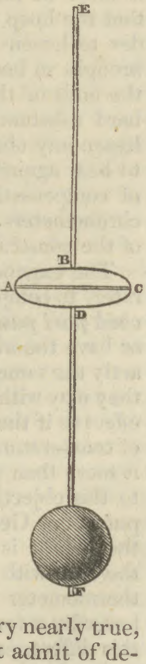
Mr Adam Reid's compensation has a very long central rod of steel descending considerably below the bob, and has this lower part covered by a zinc tube. The bottom of the zinc rests on a nut fixed on the lower end of the rod, while the bob, again, rests on the top of the zinc tube. Hence, if the zinc, by expanding upward, raise the centre of oscillation as much as the downward expansion of the long steel rod depresses it, a compensation will be effected. The length of this pendulum exposes it to much resistance from the air; and the zinc being so low down, is apt to differ materially in temperature from the steel rod. Captain Kater's pendulum of 1808, noticed below, is older than this, and only differs from it in having a wooden rod.

Somewhat allied to the last is the very home-made kind of pendulum consisting of a wooden rod partly covered by a leaden tube, and which has often received far more than its due share of commendation. Pendulums with wooden rods are described by Captain Kater, in Nicholson's Journal for 1808, and in the volume on Mechanics in Lardner's Cyclopædia; by Colonel Beaufoy, in the Annals of Philosophy for March 1820; by Mr Baily, in vol. i. Memoirs of Astronomical Society; by Mr Squire, in Philosophical Magazine for January 1825 and July 1827; and by Professor Stevelly, in the Reports of the British Association (vol. v.). This last, though professedly written in refutation of the rules given by Captain Kater and Mr Baily for the construction of compensating pendulums, is itself far from being correct; for Mr Stevelly only takes into account the expansion of the wood in so far as it affects the position of the lead, and quite overlooks it as affecting the position of its own mass; so that he provides no compensation for the wooden part of his pendulum, although he is to have such a mass of wood at the lower end of the rod that the wooden part alone is to vibrate in a second when there is no lead on it at all.

Mr Baily, probably including the suspension spring, makes the rod of deal 45·75 inches long and 0·375 in diameter; the tube of lead 14·3 inches long and from 1·25 to 2·25 inches diameter outside, with a bore just sufficient to hold the rod. Mr Stevelly uses a suspension spring two inches long; a deal-rod 44·995 inches long and 0·6 diameter; a leaden tube 16·965 inches long and 1·5 diameter outside, with a bore to fit the rod. But, without endeavouring to correct either of these rules, the safe way, we presume, is to have the tube at first too long, and then gradually to reduce it by repeated trials, because the expansion of the wood is so very uncertain. Mr Stevelly considers a bracket of wood firmly fixed on the lower end of the rod to be greatly preferable to a nut and screw for the tube to rest upon; and, to regulate the clock, he varies the length of the suspension spring in a very ingenious manner, by means of a micrometer screw, which works a nut and screw at the top of the pendulum. But of this part of the scheme we do not approve, no matter to what sort of pendulum it were applied. For we are much of the opinion which has often been advanced, that the suspension spring ought to be so contrived as to equalize the times of the wider and narrower vibrations, a great desideratum for every nice pendulum, as will be noticed more particularly afterwards. The proper length of such a spring could only be ascertained by actual trials; and if that were done, the length could not afterwards be varied without disturbing the isochronism of the vibrations. The like may be said of all those compensations whose effect depends on their varying the length of the spring, as is the case with those of Deparcieux, Julien Leroy, Fordyce, Wynn, and many others.

Although the effects of moisture in altering the dimensions and weight of the wood may be in a great measure obviated by baking, and by impregnating and coating it with certain substances, yet these again tend to increase its expansion by heat. But another objection, which applies to every pendulum in which the bob acts as the compensation, is, that the middle of the bob being far below the middle of the rod, their temperatures are apt to differ materially; and especially in this case, where the temperature of the wood must change much more slowly than that of the metal.

Bars composed of plates of two different metals, as, for instance, brass and steel soldered or riveted together, have also been used in the construction of various compensations. Thus, a bar of this sort being placed across the pendulum rod, and having the more expansible metal on the under side, carries a weight at each end. The consequence is, that a rise of temperature tends to raise the ends of the bar, together with the weights, and of course to raise the centre of oscillation; and a fall of temperature has just the opposite effect. If the bar is thin, it is apt to be in a state of perpetual tremor; and if so thick as to obviate this, it scarcely yields under the variations of temperature. Other forms of this sort of compensation are generally very complicated.



Principle of a proposed compensation pendulum.

There are many other compensating pendulums, but the most of them are either the same in principle with those we have described, or they fall under some of the objections stated in the course of this article. We shall, therefore, only add a description of the following one, wichh we presume to be new, and free from the objections just alluded to.

If an elastic hoop of metal in the figure of an ellipse have a force applied to it, as it were, slightly, to alter the length of either axis, the length of the other axis will at the same time undergo a contrary change; and the variations of these axes will be to each other in the inverse ratio of the axes themselves. Thus, if the greater axis A C were nine inches long, and a force were applied to increase it to 9·01, the smaller axis B D, if three inches, would be reduced to 2·97; or if A C were reduced to 8·99, B D would be increased to 3·03. This property we have found by trial upon a large scale to be either accurately or very nearly true, for minute variations of the axes. Whether it admit of demonstration is not of much consequence to our present purpose. Indeed, the probability of forming a hoop of an accurately elliptical figure is not very great, and as little is the chance that it would be perfectly uniform in its stiffness. Without these conditions it would be nearly useless to attempt any demonstration.

In the annexed outline of a compensation pendulum on this principle, let the elliptic hoop A B C D be of the dimensions above stated, and of steel, while the horizontal rod A C, occupying the position of the longer axis, is of zinc; since the expansions of these metals are nearly as one to 2·7, the excess of the expansion of the zinc rod of nine inches over that of an equal length of steel would still compensate $9 \times 1{\cdot}7 = 15{\cdot}3$ inches of steel. But, by the property just described, the corresponding excess of the contraction of the shorter axis B D in the vertical direction over its own expansion, being equal to three times the expansion of those 15·3 inches of steel, will compensate 45·9 inches of the steel pendulum rod EF attached in two pieces EB, DF to the opposite sides of the hoop.

This rough computation will, we presume, be sufficient to show the efficiency of such a mode of compensation, in which, if the hoop be only pressed against the rounded ends of the zinc rod by the weight of the pendulum, there need be no friction, and consequently no moving by jerks or starts, whilst the temperature is changing. It is, besides, a great recommendation to this compensation, that the hoop will readily admit of being so placed in the pendulum rod as to have the average temperature of its different parts. The construction will be easy, and attended with little expense. Perhaps, in place of a single hoop, it might in some cases be preferable to use two of a smaller and less eccentric figure, and even to employ other metals. But since the greater the eccentricity of the ellipse, the greater, within proper limits, will be the compensating effect; and therefore, by putting in a longer or shorter rod of zinc, the effect may be easily adjusted. The compensation might be still more readily regulated by forming the zinc rod in two pieces, screwing together in the middle, and thus being capable of lengthening and shortening, like the common contrivance for stretching a hat. The length of the zinc rod, when so adjusted, together with the weight of the pendulum, will readily bring and keep the hoop to the proper eccentricity, unless it has originally been very far from it, in which case it must be altered. It would, however, be an advantage that the hoop should be rather longer than the zinc, in order to lessen the pressure on the ends of the rod, when brought to bear against it by the weight of the bob. But the ends of the rod might be capped with steel or other hard substance, which could both protect the zinc and lessen any chance of friction, by presenting a sharper point to bear against the hoop. It is evident that this principle of compensation is equally applicable to the balances of chronometers. But we cannot here enter into the details of the construction.

General remarks.

The expansion of one material cannot be expected accurately to compensate that of another, unless they either proceed *pari passu* everywhere alike exposed for temperature, or have the average temperatures of their several parts exactly the same; or at least have these parts so arranged that they may with good reason be expected to produce the same effect as if the whole apparatus underwent the same change of temperature. Now, the following considerations render it more than probable that many compensations are liable to this objection, and that they are therefore unfit for the purpose. Generally speaking, the external air is colder as the height is greater, but the reverse is more commonly the case with confined air, or that within doors; so that a thermometer near the floor often indicates a temperature lower by several degrees than another near the ceiling; and this difference is said to be greater as the weather is more inclined to rain. In an upper room the ceiling is liable to great fluctuations of temperature from the vicissitudes of the weather, and, no doubt, may occasionally be much colder than the floor. But at any rate, it is found that, even in confined air, a difference of thirty-nine inches in height, which is far short of the length of many a pendulum rod, is often attended with a sensible difference of temperature. Thus, on examining the extensive tables of Mr Baily's experiments in the Philosophical Transactions for 1832, we find that he had placed two thermometers within his vacuum apparatus, the one being at the axis of suspension of the pendulum, and the other on a level with the centre of oscillation, and that they frequently differ by half a degree and more, though the apartment was one of an uncommonly steady temperature. Generally the upper thermometer was at the higher temperature, though sometimes the reverse. In some cases the air was of the full pressure, in others nearly exhausted. There is likewise reason to fear, that a difference frequently exists between the temperature of a pendulum rod and that of the parts compensating it, when the latter are separate from the pendulum and at rest, and especially when they are at some distance from it, with perhaps some board, stone, or partition intervening When a tube encloses one or more rods or tubes, it may be expected to partake sooner of any change in the air's temperature than the parts within; and still more will this be the case where several tubes successively incase one another. Besides, different materials differ greatly in the promptitude with which they acquire a change of temperature. Marble, mica, glass, and even earthenware, have sometimes been used for pendulum rods. But such substances, if slender, are extremely liable to be broken; and if thick, they are apt, from their being very bad conductors of heat, to take longer time in changing their temperatures than the other parts of the pendulum which are to form the compensation; hence, none of these materials can be compared with the metals. It is likewise to be feared that some of these will be liable to have their weights continually varying with the changes of humidity. Still more objectionable are vegetable or animal materials, owing to their changeable texture, and the perpetually varying effects of heat and moisture in altering their dimensions and weights in an uncertain manner.

Sudden alternations in the temperature of a pendulum might surely be in a great measure prevented by making the clock-case of double boards, with a small space between them, which might be either left empty, or filled with some bad conductor of heat. But we very much doubt if this, or any other simple method, could insure, that parts which are at a distance and on different levels, as, for instance, that both ends of a pendulum, would have the same temperature, the want of which is a serious objection to many a compensation, not excepting the mercurial pendulum. In all cases in which the parts of the pendulum slide or turn with friction under considerable pressure, the compensation is apt either not to act at all, or to be too long in moving, and then to go too far by a start or jerk.

Equa tion times differ arcs.

We have noticed above, and also in the article Clock-work, that the vibrations of a pendulum naturally occupy more time in the wider arcs of the same circle than in the narrower. But since the width of the vibrations is liable to be considerably affected by the state of the oil and the degree of foulness of the clock, it would be of great consequence that the rate of the clock should be rendered independent of the variable extent of the arc, because without this every compensation, whether for temperature or pressure, must at times fail to some extent, though it would only be worth the while to equalize the times in a clock having a dead beat, or detached scapement, or one whose rate is otherwise independent of any inconstant action of the wheels upon the pendulum.

Smith, in his Horological Disquisitions, published in 1694, alleged that it is possible to form the spring of suspension such that it would equalize the times of wider and narrower vibrations. The same idea was afterwards advanced by Peter Leroy, in a memoir published in 1770; and again by Berthoud, in his *Supplément au Traité des Montres à Longitude*, 1807, where he says, "la suspension à ressort bien construite tend à rendre isochrones les oscillations du pendule." In the Philosophical Magazine for April 1833, Mr Scrymgeour has given an account of his trying this with success upon the pendulums of two clocks, both of which had dead-beat scapements. The one pendulum had a wooden rod and a common lenticular bob of four pounds, with a brass ball under it of half a pound. The suspending spring was originally about three fourths of an inch long, and of a middling strength. It was then in effect shortened by fixing on each side of it a piece of steel, which was also joined to the rod. Mr Scrymgeour found, that when the length of the acting part of the spring was by this means reduced to about an eighth of an inch, the time in an arc of 3° did not differ more than half a second in twenty-four hours from that in an arc of 5°. The other pendulum was a mercurial one, with a suspending spring nearly half an inch broad and ·0083 thick. A moveable clamp was made to fasten near the top of the rod, so as to be shifted up and down at pleasure, and to clasp the spring. The times in different arcs were found to be equalized when the length of the acting part of the spring was reduced to about one twentieth of an inch. After both clocks had been kept going for a considerable time, they had lost in their rate, which Mr Scrymgeour ascribes to the gradual weakening of the spring. In this he was probably right; and if so, it seems also to show that the springs were too soft, otherwise they would rather have broken than shown any symptoms of losing their force. The usual and needless practice of softening the ends of the spring, that it may be more easily pierced for the rivets, was very likely the cause of this. However, the springs may likewise have at length acquired a little play in the slits in which they were held. For, after all, we suspect that this property of isochronism in so short a spring must have been in a great measure owing to its coming to act more closely against the corners of both slits, when the pendulum vibrated in larger arcs than in smaller. A much longer and stiffer spring, when curved into an arc of 2°, or of half a vibration, might tend to shorten the pendulum, though by an almost inappreciable quantity; but this seems nearly out of the question with a short slender spring. Neither does Hooke's law of the force of a spring being as the tension at all account for it.

We have sometimes thought, that if two pieces of a slender spring were laid together, and firmly held at both ends, the compound spring so formed would have the property of transgressing Hooke's law, so as to have its force increasing in a higher ratio than the tension. For, whilst bending at first very slightly, the one part of this compound spring would not sensibly interfere with the action of the other, and so the force of both would be only double that of either singly; but as the curvature increased, the one part would, as it were, become too long for the other, and so their joint force would be more than double that of either separately. In this way the force would increase faster than the arc of vibration, which is just the thing wanted. Such a spring would obviously break or be wrinkled useless, if it were forced through a large arc, but would safely bear to be bent through arcs more than sufficiently large for the purposes of the pendulum.

As some clocks, in place of altering the bob, are regulated by having a small weight to shift along the pendulum rod, which was a contrivance of Huygens, it may be useful here to show, that the effect of such regulating weight to accelerate the clock is greatest when it is exactly halfway between the axis of suspension and the centre of oscillation; because, unless this is kept in view, the shifting the weight upward may really make the clock go slower instead of faster, and *vice versa*. Let A be the sum of the products of all the particles of the pendulum, except those of the moveable weight, into the squares of their distances respectively from the axis of suspension, and let B be the sum of all the products of the same particles into their simple distances from that axis; also, let C be the moveable weight at the variable distance x from the axis of suspension. Since the greatest acceleration will occur when y, the effective length of the pendulum, is a minimum, and since, by the well-known property of the pendulum, $y = \frac{\mathrm{A} + \mathrm{C}\,x^2}{\mathrm{B} + \mathrm{C}\,x}$, its fluxion will then be $= 0$; or $2(\mathrm{B} + \mathrm{C}x)\,\mathrm{C}x\,dx - (\mathrm{A} + \mathrm{C}\,x^2)\,\mathrm{C}\,dx = 0$. From this we obtain $x = \pm\sqrt{\left(\frac{\mathrm{B}^2}{\mathrm{C}^2} + \frac{\mathrm{A}}{\mathrm{C}}\right)} - \frac{\mathrm{B}}{\mathrm{C}}$. Substituting now the positive value of x in the above expression for y, and reducing, it will be found that the value of y is just double that of x, or that $x = \frac{1}{2}y$. This question is treated in a very different manner, and at great length, in the *Connaissance des Tems* for 1817, by Baron de Prony, who recommends this mode of regulating, because the small weight admits of being shifted over a much more appreciable space than the bob does, and because it may be placed so high on the rod as to be readily shifted without stopping the clock. If placed above the middle of the effective length of the whole pendulum, it must be moved downward to make the clock go faster, and upward to make it go slower.

Mr Browne's mode of regulating consists in having some convenient surface so situated on the pendulum, that crooked bits of lead may either be readily put on it or removed, without disturbing the motion of the clock.

Pendulum for determining the density of the earth.

The British government has lately granted a sum of money towards defraying the expenses of repeating Cavendish's experiment for determining the mean density of the earth, and the apparatus is in the course of being constructed. But we have often thought that in this case (as well as in that proposed under the article Clock-work, vol. vi. p. 784, for determining the velocity of sound), the application of clock-work might furnish a more systematic mode of settling the question. If two accurate clocks, perfectly equal in every respect, and provided with very long pendulums, but without any compensations, were adjusted to the same rate; then, by placing one or more great masses of lead near to the ball of the one pendulum, the effect of this on its rate, if at all appreciable, would be very accurately pointed out by the difference in the times shown by the two clocks. The spaces in which the two pendulums moved could still be kept exactly equal, by placing equally near the other pendulum patterns of the lead, but formed of some light substance. In this way, with proper precaution to have both clocks at the same, though perhaps a variable, temperature, no corrections for temperature or pressure would be required, and the two clocks, left to themselves, would repeat the experiment thousands of times, and register the amount. By making the ball of the pendulum vibrate through a massy ring of lead placed vertically, with a slit at the top to make way for the rod, the clock should be accelerated. This acceleration, together with the extent of the vibrations, and the masses and dimensions of the ring and pendulum, would furnish data for computing the attraction and mass of the earth in terms of those of the ring. If the lower end of the pendulum rod were formed into a sufficiently large loop linking into the ring, it might move clear of it without the lead having any slit. But there are various other forms in which the lead might be presented to the pendulum, either to accelerate or retard it. Nay, masses might be so placed as to accelerate the one clock and retard the other.

Hardy's inverted pendulum.

Hardy's inverted pendulum, represented in fig. 7, Plate CCCCIII. is similar to an ordinary clock pendulum having a spring suspension, but only inverted. It is also furnished with a weight, which can be shifted along the rod, to render its vibrations of any required duration. This instrument has been much used by Captain Kater and others as a test for the steadiness of the supports on which their pendulums were swung; because its sensibility was believed to be such, that the slightest vibration of any thing on which it stood would set it a nodding. But the following consideration has led us to doubt its extreme sensibility, and therefore also to question whether the discrepancies in some pendulum experiments may not have been owing to the unbounded confidence reposed in this instrument. The spring which supports the rod, and connects it with the pedestal, must be incomparably more stiff in proportion to the mass of the pendulum, than is usual with springs of suspension; otherwise this pendulum would to a certainty lean over to one side, or fall down altogether. Such a stiff spring must therefore render the instrument quite insensible to any very slight vibrations of the article on which it is set. Another defect is, that the force of gravity acts upon it in the most disadvantageous manner, and makes the durations of the vibrations increase prodigiously with their width. From such considerations, we should be disposed to reject this form of instrument altogether, as not being a trustworthy test for the steadiness of supports. All we would retain of it is the mere frame, from the top of which, if a leaden ball were suspended by a thread or fine wire, it would be possessed of far greater sensibility, would have its wide and narrow vibrations nearly isochronous, and would join in or comply with the vibrations of the support, whatever might be their direction; whereas Hardy's instrument can only act in a single plane. The thread, too, could most readily have its length altered, so as to fit it for commencing its vibrations in accordance with those which might be suspected in any support.

In addition to the various references and authorities which have been mentioned in the course of this article, and in that on CLOCK-WORK, we beg to refer to the different scientific periodicals, and to the accounts of the various expeditions which have been more recently undertaken for purposes of scientific investigation. (E. E. E.)

PENELLA, a town of the kingdom of Portugal, in the province of Beira, and corregimiento of Cambra. It is situated upon an elevated spot, and is defended by two castles. It contains two churches, an hospital, and a poorhouse, 746 dwellings, and 3760 inhabitants.

PENELOPE, in fabulous history, the daughter of Icarus, married Ulysses, by whom she had Telemachus. During the absence of Ulysses, who had gone to the siege of Troy, and who staid twenty years from his dominions, several princes, charmed with Penelope's beauty, told her that Ulysses was dead, offered to marry her, and pressed her to declare in their favour. She promised compliance on condition that they would give her time to finish a piece of tapestry she was weaving; but at the same time she undid in the night what she had done in the day, and by this artifice eluded their importunity till Ulysses's return.

PENETRALE, a sacred apartment or chapel in private houses, which was set apart for the worship of the household gods amongst the ancient Romans. In temples also there were *penetralia*, or apartments of distinguished sanctity, where the images of the gods were kept, and certain solemn ceremonies performed.

PENGUIN ISLAND, a small island near the coast of New Holland, at the entrance of Adventure Bay. Long. 147. 33. E. Lat. 43. 21. N.

PENICHE, a city of Portugal, in the province of Estremadura, and corregimiento of Leiria. It stands upon a peninsula, which is divided from the continent by a narrow channel, at times nearly dry. It is fortified and protected by a citadel called Amparo, and also by a fort on Cape Carooeiro. It contains three churches, a monastery, a hospital, a poor-house, 920 dwelling-houses, and 4800 inhabitants. In the harbour, which is small, there is depth of water sufficient for large ships. The fishery affords occupation to the greater portion of the population.

PENIGK, a city of the kingdom of Saxony, in the circle of the Erzgebirge, and the capital of the patrimonial bailiwick of the same name. It is situated on the river Mulde, and contains 440 houses, with 3450 inhabitants. It has a palace belonging to the mediatized count. The chief occupation consists in making and printing cotton goods.

PENINSULA, in *Geography*, is a portion or extent of land joining to the continent by a narrow neck or isthmus, the rest being encompassed with water.

PENISA, a town of Spain, in the partida of Denia, and the province of Valencia. It contains 3200 inhabitants, who are chiefly occupied in drying raisins for distant countries, an article which is peculiarly excellent in its quality, being the growth of the vicinity.

PENISCOLA, a city of Spain, in the province of Valencia, and the capital of a department of the same name, which runs along the coast of the Mediterranean, in the north-east part. The city stands on a hill which runs out into the sea. It has a citadel, and is surrounded with walls. This place is remarkable for the purity of the air. The inhabitants amount to 3000, a great part of whom are employed in the fisheries. The fields are not so well cultivated as in most other parts of the province. Long. 0. 23. 25. W. Lat. 40. 22. 40. N.

PENITENCE is sometimes used for a state of repentance, and sometimes for the act of repenting. It is also used for a discipline or punishment attending repentance, more usually called *penance*. Besides, it gives title to several religious orders, consisting either of converted debauchees and reformed prostitutes, or of persons who devote themselves to the office of reclaiming them. Of this latter kind is the

Order of PENITENCE *of St Magdalen*, established about the year 1272 by one Bernard, a citizen of Marseilles, who devoted himself to the work of converting the courtezans of that city. Bernard was seconded by several others, who, having formed a kind of society, were at length erected into a religious order by Pope Nicholas III. under the rule of St Augustin. F. Gesnay says that they also constituted a religious order of the penitents, or women they converted, giving them the same rules and observances which they themselves followed.

PENITENTIAL, an ecclesiastical book, retained among the Catholics, in which is prescribed what relates to the imposition of penance and the reconciliation of penitents. There are various penitentials, as the Roman penitential, that of the venerable Bede, that of Pope Gregory III. and several others.

PENITENTIARY, in the ancient Christian church, a name given to certain presbyters or priests, appointed in every church to receive the private confessions of the people, in order to facilitate public discipline, by informing them what sins were to be expiated by public penance, and to appoint private penance for such occult crimes as were not proper to be publicly censured.

Penitentiary, at the court of Rome, is an office in which are examined and delivered out the secret bulls, graces, or dispensations relating to cases of conscience, confessions, and the like.

Penitentiary, a prison or place of confinement for criminals, in which the prisoners are made to labour, and a system of discipline is employed for effecting their reformation. See Prison and Prison-Discipline.

PENJINE, a river of Asiatic Russia, near the north-eastern extremity of the government of Irkoutsk. Its origin and course is but imperfectly known.

PENKRIDGE, a market-town situated within the hundred of Cuttlestone, in the county of Stafford, 129 miles from London. It stands on the river Penk, and has a market, which is held on Saturday. It is a very ancient town, being supposed to have been the *Pennocrucicum* of the Romans; but it has very little trade. The population amounted in 1801 to 1133, in 1811 to 1934, in 1821 to 2299, and in 1831 to 2351; but the parish, which is more extensive, appears by the last census to have contained 2991 persons.

PENMAN-Mawr, a mountain in Caernarvonshire, 1400 feet in height. It hangs perpendicularly over the sea, at so vast a height, that few spectators are able to look down the dreadful steep. On the side which is next the sea, there is a road cut out of the side of the rock, about six or seven feet wide, which winds up a steep ascent.

PENN, William, an eminent writer amongst the Quakers, and the planter and legislator of Pennsylvania, was the son of Sir William Penn, and born at London in the year 1644. In 1660 he was entered a gentleman of Christ-Church, in Oxford; but having previously received an impression from the preaching of one Thomas Loe, a Quaker, he withdrew, with some other students, from the national worship, and held private meetings, where they preached and prayed amongst themselves. This having given great offence to the heads of the college, Mr Penn, although only sixteen years of age, was fined for non-conformity; and, continuing his religious exercises, he was at length expelled the college. Upon his return home, he was on the same account treated with great severity by his father, who at length turned him out of doors; but his resentment afterwards abating, Penn was sent, in company with some persons of quality, to France, where he continued for a considerable time, and returned not only well skilled in the French language, but a polite and accomplished gentleman. About the year 1666, his father committed to his care a considerable estate in Ireland. Being found in one of the Quakers' meetings in Cork, he, with many others, was thrown into prison; but having written to the Earl of Orrery, he was soon after discharged. However, his father being informed that he still adhered to his opinions, sent for him to England, and finding him unmoved by all his arguments, turned him out of doors a second time. About the year 1668, he became a public preacher amongst the Quakers, and in that year was committed close prisoner to the Tower, where he wrote several treatises. Being discharged after seven months' imprisonment, he went to Ireland, where he also preached amongst the Quakers. Returning to England, he was, in 1670, committed to Newgate for preaching in Gracechurch Street meeting-house, London; but being tried at the sessions-house of the Old Bailey, he was acquitted. In September the same year his father died, and, being perfectly reconciled to his son, left him both his paternal blessing and a good estate. But his persecutions were not yet at an end; for in the year 1671 he was committed to Newgate, for preaching at a meeting in Wheeler Street, London; and during his imprisonment, which continued six months, he also wrote several treatises. After his discharge he went into Holland and Germany; and, in the beginning of the year 1672, married and settled with his family at Rickmansworth, in Hertfordshire. The same year he published several pieces, and particularly one against Reeve and Muggleton. In 1677 he again travelled into Holland and Germany, in order to propagate his opinions, and had frequent conversations with the Princess Elizabeth, daughter to the Queen of Bohemia, and sister to the Princess Sophia, mother of George I. In the year 1681, Charles II., in consideration of the services of Mr Penn's father, and several debts due to him by the crown at the time of his decease, granted Mr Penn and his heirs the province lying on the western side of the river Delaware, in North America, which thence obtained the name of *Pennsylvania.* Upon this Mr Penn published a brief account of the province, together with the king's patent; and proposing an easy purchase of lands, and good terms of settlement, for such as were inclined to remove thither, he induced many to proceed to the new settlement. These having made and improved their plantations to good advantage, the governor, in order to secure the planters from the native Indians, appointed commissioners to purchase the land which he had received from the king of the native Indians, and concluded a peace with them. The city of Philadelphia was planned and built; and he himself drew up the fundamental constitutions of Pennsylvania, in twenty-four articles. In 1681 he was elected a member of the Royal Society; and the next year he embarked for Pennsylvania, where he continued about two years, and returned to England in August 1684.

Upon the accession of James II. to the throne, he was taken into a great degree of favour with his majesty, which exposed him to the imputation of being a Papist; but from this he fully vindicated himself. However, upon the Revolution, he was examined before the council in 1688, and obliged to give security for his appearance upon the first day of next term, which was afterwards continued. He was several times examined and discharged; and at length warrants being issued out against him, he was obliged to conceal himself during two or three years. But being at last permitted to appear before the king and council, he represented his innocence so effectually that he was acquitted. In August 1699, he, with his wife and family, embarked for Pennsylvania, whence he returned in 1701, in order to vindicate his proprietary right, which had been attacked during his absence. On Queen Anne's accession to the crown, he was in great favour with her majesty, and often at court. But in 1707 he was involved in a law-suit with the executors of a person who had formerly been his steward; and, though many thought him aggrieved, the Court of Chancery did not deem it proper to afford him any relief; upon which account he was obliged to live within the rules of the Fleet for several months, till the matter in dispute was accommodated. Penn died in the year 1718.

At one period of his life Penn lodged in a house in Norfolk Street, in the Strand. In the entrance to it he had a peeping-hole, through which he could see any person who came to him. A creditor one day sent in his name, and having been made to wait more than a reasonable time, he knocked for the servant, whom he asked, "Will not thy master see me?" "Friend," answered the servant, "he has seen thee, but he does not like thee." Mr Penn's friendly and pacific manner of treating the Indians produced in them an extraordinary love for him and his people; so that they maintained a perfect amity with the English settled in Pennsylvania. He was the great bulwark of the Quakers, in defence of whom he wrote numberless pieces. The most esteemed of these are, 1. His Primitive Christianity revived; 2. His defence of a paper entitled *Gospel Truths, against the exceptions of the Bishop of Cork;* 3. His Persuasive to Moderation; 4. His Good Advice to the Church of England, Roman Catholic, and Protestant Dissenter; 5. The Sandy

Penn.

Foundation shaken; 6. No Cross, no Crown; 7. The great case of Liberty of Conscience debated; 8. The Christian Quaker and his Testimony stated and vindicated; 9. A Discourse of the general Rule of Faith and Practice, and Judge of Controversy; 10. England's Present Interest considered; 11. An Address to Protestants; 12. His Reflections and Maxims; 13. His Advice to his Children; 14. His Rise and Progress of the People called *Quakers;* 15. A Treatise on Oaths. Most of these have passed through several editions, some of them many. The letters between William Penn and Dr Tillotson, and William Penn and William Popple, together with Penn's letters to the Princess Elizabeth of the Rhine, and the Countess of Hornes, as also one to his wife on his going to Pennsylvania, are inserted in his works, which were first collected and published in two volumes folio; and the parts since selected, and abridged into one volume folio, are deservedly admired for the good sense by which they are characterized.

PENNANT, THOMAS, a celebrated naturalist, was born in Flintshire, about the year 1726. His family had their residence in that country for several hundred years; and he himself informs us that he acquired the rudiments of his education at Wrexham, whence he was sent to Fulham. Not long after this he went to the university of Oxford, where his progress in classical knowledge was very considerable, after which he turned his attention to the study of jurisprudence; but it is nowhere said that he ever followed the law as a profession.

We are informed that his taste for natural history, by his knowledge of which he afterwards became so conspicuous, was first excited by the perusal of Willughby's Ornithology, a copy of which had been sent him in a present. He began his travels at home, which was certainly the most proper step, to acquire a knowledge of the manners, curiosities, and productions of his native country, before he attempted to delineate those of any other nation. He then visited the Continent, where he acquired additional knowledge respecting his most favourite studies, and became acquainted with some of the most celebrated literary characters which that period produced. When he returned home he married, and had two children; but he was thirty-seven years of age before he gained possession of the family estate, after which he took up his residence at Downing.

On the death of his wife he again set out for the Continent, where he became acquainted with Voltaire, Buffon, Pallas, and other eminent characters. Being an author as early as the year 1750, when only twenty-four years of age, he had acquired a considerable degree of reputation in that capacity by the time he became acquainted with the above-mentioned philosophers. His reputation as a naturalist was established by his British Zoology, in four volumes 4to; and still further increased by his epistolary correspondence with no less a personage than Linnæus. He undertook a tour to Cornwall at an early period of life, and also felt an irresistible propensity to survey the works of nature in the northern parts of the kingdom. For this purpose he set out for Scotland in 1771, and published an amusing account of his tour, in three volumes 4to, which was destined to receive such a share of public favour as to pass through several editions. His Welsh tour was published in 1778, and his journey from Chester to London in 1782, in one volume 4to. About the year 1784 appeared his Arctic Zoology, a work which was very much esteemed, both in his own and in many other countries. He also gave the world a natural history of the parishes of Holywell and Downing, within the latter of which he had resided during more than fifty years. Not long before his death appeared his View of Hindustan, in two volumes 4to, to undertake which, it seems, he had solicitations from private friends, as well as the wishes of persons entirely unknown to him, which were expressed in the public prints. This was unquestionably a very bold attempt in a man who was turned off seventy, a period at which the faculties of the mind must certainly be impaired, especially when exerted with vigour for such a number of years before. Notwithstanding his great age, however, the work is executed in an able manner, bearing a strong resemblance to the introduction of his Arctic Zoology.

He also published a letter on the earthquake which was felt at Downing in Flintshire, in the year 1753; another which was inserted in the Philosophical Transactions in 1756; his Synopsis of Quadrupeds in 1771; a pamphlet on the militia; a paper on the turkey, and a volume of miscellanies.

Pennant was enabled to exhibit the greatest hospitality at his table, in consequence of the ample fortune which had been left him at his father's decease; and he gave the profits arising from the sale of several publications to charitable endowments. By his generous patronage a number of engravers met with great encouragement, and he contributed not a little to the promotion of the fine arts. About the age of fifty he married for the second time, a Miss Mostyn, sister of his neighbour, the late Sir Roger Mostyn of Flintshire. The concluding part of his life was cheerful, and it may be affirmed that he scarcely felt the advances of old age. He died at his seat at Downing in 1798, in the seventy-second year of his age.

Pennant inherited from nature a strong and vigorous constitution; his countenance was open and intelligent; his disposition was active and cheerful; and his vivacity, both in writing and conversation, made him perpetually entertaining. His heart was kind and benevolent, and in the relations of domestic life his conduct was highly worthy of imitation. The distresses in which his poor neighbours were at any time involved gave him unfeigned uneasiness, and he endeavoured to relieve them by every means in his power. He was possessed of candour, and free from common prejudices, a truth fully evinced in all his publications. The people of Scotland were proud to confess that he was the first English traveller who had fairly represented their country, in its favourable as well as in its less pleasing appearances. His style is lively, and fitted to convey the ideas which he intended to express, but it is not always correct. In zoology his arrangement is judicious, and his descriptions characteristic. If we discover several traces of vanity in those works which he published near the close of life, it ought to be remembered that it is the vanity of an old man, which is seldom disagreeable, especially when united with amiable manners and a benevolent disposition.

PENNAR, a river of Hindustan, which has its source not far from Nundydroog. It flows at first in a northerly direction until it approaches Gooty, and then takes a south-east course by Gandicotta and Cuddapah; after which it reaches the sea at Gungapatnam by an easterly course, after passing the fortress of Nelloor.

PENNATORE, a town on the sea-coast of Travancore, where the rajah of Travancore constructed a harbour for European and Chinese ships, which anchored in order to load with pepper. Long. 76. 55. E. Lat. 8. 25. N.

PENNE, a city of France, in the department of the Lot and Garonne, and the arrondissement of Villeneuve d'Agen. It stands on an elevation on the left bank of the river Lot, and contains, with its parish, 6230 inhabitants.

PENNY, in commerce, an ancient English coin, which had formerly considerable currency, but is now generally dwindled into an imaginary money or money of account. Camden derives the word from the Latin *pecunia*, money. The ancient English penny, penig, or pening, was the first silver coin struck in England; nay, the only one current amongst our Saxon ancestors, as is agreed by Camden, Spelman, Hickes, and others. The penny was equal in weight to our threepence; five of them made one shilling, or scilling Saxon, and thirty a mark or mancuse, equal to 7s. 6d. Till the time of King Edward I. the penny was struck with a cross, so deeply indented in it that it might be easily broken and parted, on occasion, into two parts, which were thence called *half-pennies;* or into four, which were called *fourthings* or *farthings.* But that prince coined it without indenture, instead of which, he first struck round halfpence and farthings. He also reduced the weight of the penny to a standard, ordering that it should weigh thirty-two grains of wheat, taken out of the middle of the ear. This penny was called the *penny sterling;* and as twenty of these pence were to weigh an ounce, the penny thus became a weight as well as a coin. The penny sterling was long disused as a coin, and was scarcely known, except as a money of account, containing the twelfth part of a shilling; but latterly it has been introduced into the British current coin.

PENNYWEIGHT, a Troy weight, containing twenty-four grains, each grain weighing a grain of wheat, gathered out of the middle of the ear, and well dried. The name took its rise from the circumstance that this was anciently the weight of one of our silver pennies.

PENORCON, an old musical instrument of the guitar kind, with nine strings and a broad finger-board.

PENRITH, a market-town and parish in the ward of Leath, in the county of Cumberland, 284 miles from London, and seventeen from Carlisle. It is an ancient town, which in the wars between England and Scotland frequently changed masters; and near to the town, on the bank of the river Emont, are now shown two curious caverns, said to have been occupied by the peaceable inhabitants during the frontier excursions of the two nations. The parish church is a handsome structure, of old date, but modernized. There are markets, which are held on Tuesday and Saturday; and there are some manufactories for woollen and cotton goods. The population amounted in 1801 to 3801, in 1811 to 4328, in 1821 to 5385, and in 1831 to 6059; but in it is included that of the whole parish, comprehending the townships of Burrogate, Dockray, Middlegate, Sandgate, Carelton, Nether-end-bridge, and Plymton.

PENRYN, a borough-town of Cornwall, in the hundred of Kerrier and parish of St Gulvian, 266 miles from London and three from Falmouth, with the harbour of which it has a water communication. It has a corporation, with twelve aldermen, twelve common-council men, and a recorder; and it continues to return two members to the House of Commons. It has considerable trade in the pilchard and Newfoundland fisheries, and in Cornish granite, which is found in abundance around it. There are markets, which are held on Wednesdays, Fridays, and Saturdays. The population amounted in 1801 to 2324, in 1811 to 2713, in 1821 to 2933, and in 1831 to 3521.

Pennsylvania.

PENNSYLVANIA, one of the United States of North America, and, in point of manufactures, the most important in the Union. As now limited, it extends from 39. 43. to 42. 16. of north latitude, and from 74. 35. to 80. 31. of longitude west from Greenwich. It is bounded on the north by New York; on the east and north-east by the river Delaware, which separates it from New Jersey; on the south-east by the state of Delaware; on the south by Maryland and part of Virginia; and on the west by the latter state and part of that of Ohio. Darby, in his Geographical View, makes its greatest length to be 315 American statute miles, and its greatest breadth 176 miles, thus comprehending an area of about 47,000 square miles, or 30,080,000 statute acres. The most prominent natural features which strike the eye at the first glance of a map of Pennsylvania are the mountains. Scarcely any part of it is entitled to be called level; and it may be doubted whether a more widely-diversified region exists upon the face of the earth, or one of similar area in which the vegetable and mineral productions are more numerous. The Appalachian range in the United States generally extends in a direction deviating not very essentially from the south-west to the north-east; but in Pennsylvania the whole chain is deflected from that course, and traverses the state in a serpentine direction. Towards the southern boundary, the mountains run nearly north-north-east, but gradually incline more eastwardly as they penetrate northward; and in the central counties many of the chains run nearly east and west. But as they approach the northern limits of the state they again gradually incline to the north-east, and enter New York and New Jersey nearly in that direction. The principal ridges are the Blue Mountains, behind which, and nearly parallel with them, are other smaller ridges. On the west side of the Susquehannah are the Kittatinny ridges, which are succeeded by the great Alleghany ridge, the largest of all, and which gives name to the whole system. West of these mountains, Pennsylvania consists of hill, dale, and plains, having a surface not unlike to that of New England. In respect to surface, this state is divisible into three natural sections, viz. first, a small but important hilly tract between the marine alluvium and the lower ridges of the Appalachian system, which is called the eastern section, and comprises 7869 square miles; secondly, the mountainous or middle section, comprising 25,189 square miles; and, thirdly, the western or hilly section, comprising 13,942 square miles. The highest peaks of the Alleghanies are elevated from 2000 to 3000 feet above the level of the sea. This middle region, chiefly occupied by Germans, presents all varieties of scenery, the grand, rugged, and romantic, blending with the sheltered, the beautiful, and the cultivated. Some of the mountains admit of cultivation almost to their summits, and the valleys between them are in general rich and fertile.

The principal rivers are the Delaware, the Susquehannah, Schuylkill, Lehigh, Alleghany, Monongahela, Ohio, Juniatta, Youghiogeny, and Clarion, formerly called Toby's Creek. The Susquehannah is the largest Atlantic river of the United States. It rises in the state of New York, near the sources of the Mohawk, and, flowing in a south-westerly direction, enters Pennsylvania, but afterwards bends its course back into New York. Still seeking an outlet to the west, it returns into Pennsylvania, and receives the Tioga River, the West Branch, and the Juniatta. These accumulated waters swell it to a broad stream, which, passing Harrisburgh, enters Maryland, and finds its estuary in Chesapeake Bay, at Havre-de-Grace, after a course, measuring its curves, of more than five hundred miles. It has a number of tributaries, the largest of which is the Juniatta. This stream has its origin in the Alleghanies, from two large branches which rise a little above Huntingdon. The united river divides again, and by two mouths enters the Susquehannah fourteen miles above Harrisburgh. Lehigh is an important branch of the Delaware. It finds its way through several hills, and, amongst others, through the Blue Ridge. After passing the Moravian towns and a beautiful country, it falls into the Delaware at Easton. The canals have enabled the great cities to avail themselves of the rich and exhaustless coal-beds near its banks. Schuylkill rises amongst the mountains of Schuylkill county, and, winding through a rich country, and the towns of Reading and Pottstown, supplying Philadelphia with water in its course, it falls into the Delaware about seven miles below the commercial metropolis of Pennsylvania. It has a long course; and the locks and canals have rendered it navigable, so that the immense beds of anthracite coal at its head sources are rendered available to Philadelphia and the country on the coast.

Pennsylvania.

Besides these main streams, Pennsylvania is watered by numerous large creeks and rivulets to as great a degree as any equal extent of country in the United States. Many of these, besides irrigating and fertilizing the rich interior of the state, likewise furnish admirable water power.

The soil of Pennsylvania is much diversified. In some parts it is barren, but a great proportion of it is fertile, and not a little very excellent. West of the mountains the soil of the first quality is a deep black mould, equal in fertility to that of any part of the United States. Pennsylvania is emphatically a grain country, wheat being the most important article of produce. Indian corn, rye, buck-wheat, barley, oats, flax, hemp, beans, peas, and potatoes, are also extensively cultivated; thus, with the exception of rice, embracing all the cerealia raised in the United States. From the difference of level in the state, it admits a great diversity of other vegetable productions. Amongst fruits, apples, cherries, pears, peaches, and plums are abundant. Of indigenous forest-trees there is equal variety, including hemlock, pine, hickory, walnut, wild cherry, locust, maple, chestnut, mulberry, oak, gum, sassafras, elm, and poplar. Grapes are common, and the wild plum and crab-apple abound. In some counties foreign grapes have been advantageously cultivated, and wine and brandy of good quality have been made from them, but not to any extent. The sugar maple in the western and northern parts of the state is abundant, and sugar is made from it in sufficient quantity to supply the home consumption. Many parts of the state produce fine meadow-grass, and in these the products of the dairy are abundant. Pennsylvania is famous for its breed of draught horses; and nature has abundantly supplied the forests with game. Deer, turkeys, pheasants, and partridges, are numerous; and wild ducks are found in almost every stream. Wild geese, swans, and pigeons are migratory, and frequently found in large flocks. Bears, panthers, wild cats, wolves, and other original tenants of the forests, are more and more disappearing as settlement and cultivation extend. In the low grounds are found minks, musk-rats, and opossums; and snakes form a numerous tribe; but the bite of the rattlesnake and copperhead alone is deadly. In the eastern rivers are found rock-perch, bass, shad, and herring, which latter come from the sea in large shoals. In the western waters there is a species of cat-fish, weighing from fifty to a hundred pounds; and pike likewise of an enormous weight and size are found. Sturgeon are common to both these sections of the state. In the smaller streams trout, chub, sun-perch, mullet, white salmon, and other species of fish, are found in their several seasons.

Pennsylvania is very rich in minerals and metals. Iron ore is distributed throughout many parts of it, and the manufactures of iron are carried on to a greater extent than in any other state in the Union. Copper, lead, and alum appear in some parts; and limestone and marble, of the finest quality for the purposes of architecture and statuary, are abundant. In the middle counties anthracite, and in the western bituminous coal, are found in inexhaustible quantities. The bituminous coal-lands in Pennsylvania are estimated by a committee of the legislature of the state to comprehend an extent of 21,000 square miles, and the anthracite of 975 square miles. Since the opening of the anthracite coal trade in 1820, its average annual increase has been thirty-three per cent.; and the committee believe that it will continue to increase in the same ratio for some years to come.

During later years Pennsylvania has engaged very extensively in works of internal improvement, more so than any other state in the Union. The Pennsylvania Canal and Railroad, extending from Philadelphia to Pittsburgh, forming a connected line of communication nearly 400 miles in length, claims particular attention as a most magnificent work. Railroads have been laid out on a very extensive scale, and numerous turnpike roads and bridges have been constructed in a superior style of excellence and durability. The first turnpike road in the United States was made in Pennsylvania. At the end of 1836 the state canals in operation extended 600 miles, and the state railways 120 miles. The canals constructed by incorporated companies extended 286 miles, and the railways 106 miles. Besides these, a great number of others were in course of construction, and many of them were far advanced towards completion.

The manufactures of Pennsylvania comprehend those of cotton, woollen, iron, leather, paper, glass, ropes, and various others which supply the demand for the luxuries as well as the necessaries of life. Flour and meal also constitute important articles in the trade of this state. In the year 1831 there were in the state 67 cotton-mills, having 120,810 spindles; and there were manufactured 21,332,467 yards of cloth, with 7,111,174 lbs. of cotton used. In connection with the iron manufactures there are a vast number of blast-furnaces, air-furnaces, forges, trip-hammers, rolling and slitting mills, and naileries. In the year 1831 there were one hundred steam-engines in Pittsburgh alone. In its iron manufactures Pennsylvania far excels every other state in the Union; and, after cotton, the next in importance are those of paper and leather. The coal trade of Pennsylvania promises to be of great importance to the state, and even to the whole Union. There are three anthracite coal-mines, those of Schuylkill, Lackawana, and Lehigh. The quantity of coal taken from the first-named mine in 1834 was 224,242 tons, from the second 106,500, and from the last-named 42,700. The Lehigh mines were first wrought in 1820, the Schuylkill in 1825, and the Lackawana so late as 1829. The whole quantity shipped from the three mines, from the time when they were first opened for the market, up to the 1st of January 1836, was 2,498,024 tons. The value of the exports and imports of Pennsylvania for the year ending 30th of September 1836 was as under: Value of imports in American vessels, 14,172,453; in foreign vessels, 895,780; total, 15,068,233 dollars. Value of exports of domestic produce, 2,627,651; of foreign produce, 1,343,904; total, 3,971,555 dollars. The number of vessels which entered Philadelphia during the preceding year was, American 348, their tonnage being 68,177; and foreign sixty-eight, their tonnage being 10,816; total, 416 vessels, of 78,993 tons burden. Ship-building is carried on to a considerable extent in Pennsylvania. For the year ending 1836 there were seventy-four vessels built, their tonnage being 10,214.

The financial concerns of the state stand thus:

Receipts for the year 1836............	4,000,437·64	dollars.
Payments ditto..........................	3,675,638·11	...
Balance in the treasury..................	324,799·53	...

The public debt, relating chiefly to public improvements, was 24,970,762; and the public property, consisting principally of public works and of bank stock, was 29,106,801 dollars. From this statement it appears that the value of the property belonging to the state exceeds the amount of debt by 4,136,039 dollars. On the 1st of December 1836, the number of banks in Pennsylvania was fifty; and the capital authorized, 59,658,482 dollars; a return which, however, was not believed to be complete, though it may be considered as nearly correct. In November 1835 there were only forty-four banks, the condition of which is thus stated: Specie 3,876,868, circulation 10,932,023, deposits 13,347,977, capital 18,858,482 dollars. The amount received for postage in 1834 was 343,406 dollars, which is about 87,000 lower than that of New York, but double the sum for postage received in any other state.

The ecclesiastical statistics of Pennsylvania for the year

Pennsylvania.

1834 were as follows: Presbyterians, 475 churches; Methodist Episcopal church, 252 ministers; Evangelical Lutheran church, 312 places of public worship; German Reformed church, 150 ditto; Baptists, 157 ditto; Friends, 150 ditto; Roman Catholics, fifty-six ditto; Church of the United Brethren, eleven ditto; Associate Presbyterian church, twelve ditto; Reformed Dutch church, eight ditto; New Jerusalem church, seven ditto; Unitarians, five ditto; and the Universalists, one convention. The Lutherans, the German Reformed, the Friends, and the United Brethren, are more numerous in this state than in any other. With the exception of the Friends, whose spiritual teachers are not allowed any salary if they are at all able to support themselves without it, the ministers of religion, in general, are supported by voluntary subscriptions, contributions, and rents of pews. The facilities of receiving education in Pennsylvania are very great. The state has made grants of money and land at different times to colleges and academies, the gross amount of which is estimated at 485,000 dollars. In the year 1837, there were no less than ten colleges in Pennsylvania, besides law, medical, theological, and other schools. The university of Pennsylvania, founded in Philadelphia in the year 1755, is a highly respectable institution, embracing the departments of arts, medicine, natural science, and law. In the medical department there are seven professors, attended by above four hundred students. According to an official document published in 1837, eight of the academies which have received aid from the state report their having eight hundred and forty-one students, and a hundred and sixteen graduates, in 1836. The funds were estimated at 333,000 dollars, of which sum the property of the university of Pennsylvania alone amounts to 186,000. In three of the libraries there were 11,200 volumes. The university of Pennsylvania itself, however, possesses 44,000 volumes. There are a great number of academies and common schools, both these kinds of institutions having received considerable aid from the state funds. By the new school-laws of the state, which were passed in 1835, each county is left to determine by its votes whether it will entitle itself to the aid of the public fund, by assuming a certain proportion of the expense. The whole number of districts, according to the report already mentioned, is 987, and the number of common schools 3349. The city and county of Philadelphia constitute a school district, and are not included in the above statements. By the last annual report it appears that above 11,000 children are taught at the expense of the country. The whole number of children in the state between the ages of five and fifteen is about 320,000; but the number of scholars in the common schools is only 150,838, so that education in Pennsylvania is still somewhat limited. But when the new laws relative to this important object shall have taken full effect, a decided improvement will no doubt take place. The principal literary seminaries in this state, besides the university at Philadelphia, are, Dickinson College at Carlisle; Jefferson College at Canonsburgh; Washington College at Washington; Western University at Pittsburgh; Alleghany College at Meadville; Madison College at Union Town; Mount Airy College at German Town; the Theological seminaries at Gettysburgh, York, and Alleghany Town; and the Moravian schools at Bethlehem, Nazareth, and Litiz. By the will of a wealthy citizen of Philadelphia, who died in 1831, a fund of two millions of dollars (to be augmented, if necessary, by rents of real property, and residuary personal estate) has been appropriated for the establishment of a college for the education of orphan children. There are other benevolent institutions in the cities and towns of Pennsylvania, such as the necessities of a populous manufacturing country require; but being similar to those of New York and other large cities, they need not be particularly specified. Philadelphia is celebrated for the extent of its establishments in connection with the diffusion of knowledge. Paper-making, printing, and publishing, are carried on with great enterprise; and a vast number of gazettes, periodicals, monthlies, and quarterlies, are issued. "This city, besides, vies with Boston," says Mr Flint, "in the number and extent of its school and classical books. If Boston publishes, as regards material and execution, more substantially, Philadelphia publishes cheaper, a circumstance often as important in the extension of its books." Boston had the honour of publishing the first newspaper in the British colonies in America, which appeared in 1704. Philadelphia followed in 1719; and since that time they have multiplied in Pennsylvania more rapidly than in any other state, with the exception of New York. In the year 1834, there were published two hundred and twenty newspapers, of which thirteen were daily papers; and the number of periodical journals, of various kinds, amounted to thirty-two.

The population of the counties and county towns of Pennsylvania in 1830 was as follows:

Counties.	Population.	County Towns.	Population.
Adams	21,379	Gettysburgh	1,473
Berks	53,357	Reading	5,859
Bucks	45,740	Doyleston	1,262

The total population of Pennsylvania amounted in 1830 to 1,347,672, of whom 403 were slaves. The inhabitants are principally descended from the English, Welsh, Irish, Scotch, and Germans; besides Swedes, French, and a few Dutch. The language, in general, is English, but in many of the counties the German prevails to a considerable extent. The character of the Pennsylvanians is somewhat diversified by difference of extraction and variety of the modes of education, but this is chiefly in minor points. The law regarding aliens provides that their friends may purchase lands, tenements, and hereditaments within this commonwealth, not exceeding five thousand acres, and may have and hold the same as fully as any natural-born citizen. Such persons may also acquire, take, hold, and dispose of real estate by descent or devise, in as full and ample a manner as the citizens of the state.

The commercial capital of Pennsylvania is Philadelphia; but the political metropolis is Harrisburgh, pleasantly situated on the eastern bank of the river Susquehannah, nearly one hundred miles west from Philadelphia. At this place there is erected a covered bridge of twelve arches over the river, the construction of which cost nearly two hundred thousand dollars. The Pennsylvania Canal passes along the eastern side of the town, and forms a large basin for a harbour. Harrisburgh is regularly laid out and well built, consisting chiefly of brick. The capitol is a spacious and elegant edifice, situated on a considerable elevation on the outside of the town. The other public buildings are, a county court-house, a jail, two or three banks, a large Lancasterian school-house, about twelve places of public worship, and a number of printing offices, from six of which newspapers are issued, two of them in the German language. It has also a steam-mill, with a variety of manufacturing establishments, and is a place of considerable trade. Fifty or sixty years ago Harrisburgh was a wilderness inhabited by savages. It is now the capital of the second state in importance in the North American Union, with a population which in 1838 may be estimated at between six and seven thousand souls.

Lancaster, the capital of the richest and most fertile county in the state, is delightfully situated near Conestoga Creek, which falls into the Susquehannah sixty-two miles west from Philadelphia. It is a very healthy and flourishing city, and carries on an extensive trade with the surrounding country. The houses are well built; and amongst the numerous public edifices may be mentioned Franklin College, which was founded in 1787. There are churches, banks, schools, literary and charitable societies, sufficient for the wants of the inhabitants; and eight or nine newspapers are published in the English, and four or five in the German language. The inhabitants are mostly of German descent, and many speak the language of the land from which they sprung; but the English predominates. There are in Lancaster seventeen distilleries, and several tan-yards, breweries, and potteries. This town was laid out in the year 1730, and became early celebrated for the excellency of its stockings, saddles, and guns; it is still famous for its rifles, and the number and excellence of the stage-coaches built there. The population in 1838 was estimated at about 9000. Lat. 3. 40. N. and long. 76. 10. west from Greenwich.

Reading, also in the centre of a fine agricultural country, is situated on the east bank of the Schuylkill, and contains a number of public buildings. Being connected with Philadelphia by the line of the Pennsylvania Canal, its trade is rapidly advancing, and manufactures are also increasing. Many fine mills have been established in the vicinity, there being an ample command of water-power. The population of Reading in 1838 was reckoned at about 7500. Carlisle is an interior post-town, sixteen miles west from Harrisburgh, and 116 west from Philadelphia. It is pleasantly situated, and regularly laid out, being built chiefly of stone and brick, and it enjoys considerable trade. Dickinson College, founded here in 1783, is a flourishing institution. This town has rapidly increased, and the population in 1838 was about six thousand. Chambersburgh is situated ninety miles west from Philadelphia. The stream on which it stands furnishes water-power for many manufactories, of which the town already contains a considerable number. Blue-stone, free-stone, and marble, abound in the vicinity; and it has turnpike communications with Philadelphia, Baltimore, and Pittsburgh. The population in 1838 was estimated at above 4000. York is situated on Codoru's Creek, eighty-five miles west from Philadelphia. It is in the centre of a fertile and beautiful country, and is a handsome town, containing a number of public buildings, and a population in 1838 of above 6000. Bethlehem, Easton, Lebanon, and New Bloomfield, are all towns more or less in a flourishing state, and containing from 4000 to 8000 inhabitants.

Pittsburgh, the capital of the western district of Pennsylvania, is situated in a beautiful plain on a point of land where the Alleghany and Monongahela unite to form the river Ohio. The site of the town was early regarded as very important, and was selected by the French for Port du Quesne, one of the principal fortified places in the great chain of posts which was to connect Canada with Louisiana. It was the scene of more than one battle, and before this place Washington gained his first laurels. The name was afterwards changed to Fort Pitt, and finally to Pittsburgh. A considerable town soon rose around the fort; but the Indian wars, and the troubles of the western country, prevented its rapid growth until 1793, although the present Pittsburgh was commenced in 1765. It is now, in the extent of its manufactures, the only rival of Cincinnati in the west; and in population, wealth, and importance, it is next to that city, and the third in the valley of the Mississippi. In general the town is well built, some of the streets being handsome, and the public buildings spacious; but the whole has a gloomy or dingy aspect, from the dust and smoke of the pit-coal used in the manufactories and houses. The coal is found in the neighbourhood in inexhaustible quantities, and is easily obtained. Pittsburgh is well provided with houses of public worship for various sects, and has a public library, several banks, and a theatre. The manufacturing establishments are probably more numerous and extensive than in any other town in America in proportion to its population. In its manufactures it resembles Birmingham in England, those carried on upon a great scale being ironmongery of every description, steam-engines, and iron work in general; cutlery of all descriptions; glass and paper, cotton and woollens, pottery, chemical preparations, tin and copper ware, all which are produced to the value of 3,000,000 of dollars annually. Boat and steam-boat building have been pursued here on a greater scale than in any other town in the western country. The market is abundantly supplied, but the cost of articles is much higher than in the towns farther west on the Ohio. At low stages of the water flat and keel-boats cannot always descend the river from

Pittsburgh, which circumstance diverts to Wheeling a part of the travel to the western country; still a great part of it centres at Pittsburgh, and, in high stages of the water, steam-boats are continually arriving and departing. Pittsburgh has immense advantages in point of artificial as well as natural water communications. The great Pennsylvania Canal terminates here, and others connect it with various parts of the country. The inhabitants are a mixed race of Germans, Irish, English, Scotch, French, Swiss, and many other nations, and are distinguished for industry and economy. The Western University, founded here in the year 1820, is a thriving institution; and there are, besides, a number of seminaries of education, and benevolent societies. The suburbs of Pittsburgh are Alleghany Town, Northern Liberties, Birmingham, and Lawrenceville. Pittsburgh is the seat of justice for the county of Alleghany, and is situated in latitude 40. 32. north, and longitude 88. 0. west from Greenwich. The population of Pittsburgh, including the suburbs, may be estimated at nearly 30,000. The following observations by Mr Flint will serve to convey an idea of the importance of this state, and the rapid advances which it has made, and is still making.

"A single fact from the census of 1830 will illustrate the vigorous advance of this great state in population and importance. The aggregate increase of twenty-eight towns is sixty per cent. In 1829, 297,206 barrels of wheat flour, 39,523 of rye flour, and 1609 hogsheads and 6433 barrels of corn meal, were inspected in Philadelphia." In fact, "it spreads a wide surface in the Ohio valley, rapidly advancing in wealth and population. New towns are springing up in every direction. It abounds in all the elements of wealth and power. Public opinion has given it a strong impulse towards manufactures, and a gigantic system of internal improvements. Its inhabitants, though composed of all nations, are distinguished for their orderly habits, industry, and sober progress of thrift, and a sturdy spirit of political independence. The passing stranger, as he traverses the state, is struck with the noble roads and public works, with the beautiful German farms, and their magnificent and imperishable stone houses, and often still more magnificent stone barns. An agricultural country, alike charming and rich, spreads under his eye. He not only passes many handsome towns, but is surprised with the frequent recurrence of neat and populous villages, the names of which he had met in no itinerary or gazetteer. He sees a country of immense agricultural resources."

Pennsylvania was originally settled by a Swedish colony, which went over in the year 1638, under the government and protection of Sweden. The Dutch and Finns had likewise settled on the river Delaware, previously to the British conquest of the New Netherlands in the year 1664. In 1682, the celebrated William Penn founded a colony here, having obtained a charter from Charles II. which put him in possession of the soil and the government of the country. In the following year emigration to Pennsylvania from Wales commenced, the colonists purchasing a large extent of land, and calling the several settlements after favourite places in their native country. The Indian right was respected by William Penn, whose sense of justice induced him to make an equitable purchase from the aborigines, notwithstanding his charter; and the same policy was pursued by the constituted government after the American revolution, when the state of Pennsylvania made new purchases from the native proprietors at a fair price, and in open treaty, in the year 1784. Although the state of Pennsylvania might have considered the proprietary claims as a royalty to which the independent government could lawfully succeed, yet, as a peculiar acknowledgment of the merits and claims of William Penn and his family, the legislature offered to confirm the heirs of Penn in the title to the manor lands, which were ten per cent. of all the surveyed lands in the province, and to grant them a sum of L.130,000, which offer was accepted. This was a liberal compensation for revolutionary losses, considering that, in the year 1712, William Penn had offered to the queen of England the government and soil of the province for the sum of L.12,000; and the transference would have taken place had not an apoplectic attack rendered him incapable of completing the legal claim. A litigated question with the neighbouring state of Connecticut, touching the right of territory in the northern part of Pennsylvania, was in dependence, from the year 1750, for more than seventy years, when the public and private rights to the soil were settled in favour of this state, under conciliations and restrictions, determined by special acts of the Pennsylvania legislature, and the decisions of the supreme court of the United States. The seat of the state government was transferred from Philadelphia to Lancaster in the year 1799; and the progress of improvement and population caused it in 1812 to be removed to Harrisburgh, where handsome buildings are erected for the accommodation of the legislature and the officers of the government.

From the beginning of the eighteenth century until the commencement of the American revolution, the government was generally administered by deputies appointed by the proprietors, who were mostly resident in England. The first constitution of Pennsylvania was adopted in 1776, and the present constitution in 1790. The legislative power is vested in a general assembly, consisting of a senate and house of representatives. The representatives are elected annually on the second Tuesday in October, being apportioned according to the number of taxable inhabitants. The number cannot be less than sixty, nor more than a hundred. The senators are chosen for four years, one fourth being elected annually at the time of the election of the representatives. Their number cannot be greater than one third, nor less than one fourth, of the number of the representatives. The executive power is vested in a governor, who is elected by the people on the second Tuesday in October, and who holds his office during three years from the third Tuesday in December next following his election; and he cannot hold the office more than nine years in any term of twelve years. The general assembly meets annually at Harrisburgh on the first Tuesday in December, unless sooner convened by the governor. The judicial power is vested in the supreme court, courts of common pleas, an orphan's court, a register's court, a court of quarter sessions of the peace for each county, and in such other courts as the legislature may from time to time establish. The judges of the supreme court, and the several courts of common pleas, are appointed by the governor, and hold their offices during good behaviour. The right of suffrage is possessed by every freeman of twenty-one years of age who has resided in the state two years immediately preceding an election, and within that time paid a state or county tax, assessed at least six months before the election. It may be mentioned, in conclusion, that on the 2d of May 1837, a convention met at Harrisburgh, for the purpose of amending the constitution. What alterations were then made does not appear, but it is not probable that the essential features of the constitution have been materially changed. (R. R. R.)

PENSIONARY, or PENSIONER, a person who has an appointment or yearly sum, payable during life, by way of acknowledgment, and charged on the estate of a prince, company, or particular person.

Grand PENSIONARY, an appellation formerly applied to the first minister of the states of Holland. The grand pensionary was chairman in the assemblies of the states of that province; he proposed the matters to be consulted on, collected the votes, formed and pronounced the resolutions of the states, opened letters, conferred with foreign ministers, and performed various other functions. His business was also to inspect the finances, to maintain the authority of the states, and to see that the laws were observed; and he was perpetual deputy of the states-general of the United Provinces. His commission was, however, only given him for five years, after which it was deliberated whether or not it should be renewed; but there is no instance of its being revoked, and therefore death only put an end to the functions of this important minister.

Pensionary was also the first minister of the regency of each city in Holland. His office was to give his advice in affairs relating to the government, either of the state in general, or of the city in particular; and in assemblies of the states of the province he officiated as speaker in behalf of his city.

PENTACHORD, a musical scale consisting of five conjunct diatonic degrees. Also an instrument of five strings, according to Martianus Cappella, and other writers. Julius Pollux ascribes its invention to the Scythians.

PENTACROSTIC, in *Poetry*, a set of verses so disposed that there are always five acrostics of the same name, in five divisions of each verse.

PENTAMETER, in ancient poetry, a kind of verse, consisting of five feet or metres; and hence the name. The first and second feet may be either dactyls or spondees; the third is always a spondee; and the two last anapests. A pentameter line subjoined to an hexameter constitutes what is called *elegiac* verse.

PENTAPOLIS, a name given to the five cities, Sodom, Gomorrah, Adamah, Zeboim, and Zoar. They were all five condemned to utter destruction; but Lot interceded for the preservation of Zoar, otherwise called *Bela*. Sodom, Gomorrah, Adamah, and Zeboim, were consumed by fire from heaven; and in the place where they stood was formed the Lake Asphaltites, or the Dead Sea.

PENTATEUCH, a word derived from the Greek Πεντατευχος, from πεντε, *five*, and τευχος, an *instrument* or *volume*, and signifying the collection of the five instruments or books of Moses, which are Genesis, Exodus, Leviticus, Numbers, and Deuteronomy.

Some modern critics have disputed Moses's right to the authorship of the Pentateuch. They observe that he always speaks in the third person. "Now the man Moses was very meek above all the men which were upon the face of the earth." "The Lord spake unto Moses, saying," &c. "Moses said to Pharaoh," &c. They think that he would never have thus spoken of himself, but would at least sometimes have mentioned himself in the first person. Besides, according to these critics, the author of the Pentateuch sometimes abridges his narration like a writer who collected from some ancient memoirs, and sometimes he interrupts the thread of his discourse, as, for example, when he makes Lamech the bigamist say, "Hear my voice, ye wives of Lamech, hearken unto my speech; for I have slain a man to my wounding, and a young man to my hurt," without informing us before-hand to whom this is related. Again, when he says, "And the Canaanite was then in the land," these observations cannot be reconciled to the age of Moses, since the Canaanites continued to be the masters of Palestine during the lifetime of the Jewish legislator. The passage from the book of the wars of the Lord, quoted in the book of Numbers (xxi. 14), is supposed to have been inserted afterwards, as also the opening verses of Deuteronomy. The account of the death of Moses, which is at the end of the same book, cannot possibly belong to this legislator; and the same judgment may be formed of other passages, in which it is said that the places mentioned lay beyond Jordan, that the bed of Og was at Ramah to this day, and that the havoth of Jair, or the cities of Jair, were known to the author, though probably they did not receive that name till after Moses's time.

It is also observed, that in the text of the Pentateuch there are some places which are defective; for example, in Exodus (xii. 8) we find Moses speaking to Pharaoh, but the author has omitted the beginning of his discourse. The Samaritan inserts in the same place what is wanting in the Hebrew. In other places the same Samaritan text adds what is deficient in the Hebrew; and what it contains more than the Hebrew seems to be so well connected with the rest of the discourse, that it would be difficult to separate them. Lastly, the same critics believe that they observe certain strokes in the Pentateuch which can hardly have proceeded from Moses, who was born and bred in Egypt; as, for example, what he says of the earthly paradise, of the rivers which watered it and ran through it, of the cities of Babylon, Erech, Resen, and Calneh, of the gold of Pison, of the bdellium, and of the stone of Sohem, or onyx-stone, which was to be found in that country. These particulars, observed minutely, are supposed to prove that the author of the Pentateuch lived beyond the Euphrates; and the same conclusion may be deduced from what he says concerning the ark of Noah, of its construction, of the place where it rested, of the wood with which it was built, of the bitumen of Babylon, and other matters. But in answer to all these objections, we may observe in general, that these books are by the most ancient writers ascribed to Moses; and it is confirmed by the authority of heathen writers themselves, that they are of his writing. Besides, we have the unanimous testimony of the whole Jewish nation, ever since Moses's time, to the same effect. Direct texts of the Pentateuch imply that it was written by Moses; the book of Joshua, and other parts of Scripture, import the same thing; and though some passages have been thought to imply the contrary, yet this is but a modern opinion, and has been sufficiently confuted by several learned men. The Samaritans receive no other Scriptures but the Pentateuch, rejecting all the other books which are still contained in the Jewish canon.

PENTATHLON, in *Antiquity*, was a general name for the five exercises performed at the Grecian games, viz. wrestling, boxing, leaping, running, and playing at the discus.

PENTECONTACHORDON, an old musical instrument of the harpsichord kind, invented by Colonna, a Neapolitan, in the beginning of the sixteenth century. In it, each tone was divided into four parts, and each of these had its own peculiar wire and corresponding finger-key. The distinct wires were 500. This instrument was evidently one of the same hopeless kind that we have mentioned in the article Organ.

PENTECOST, a solemn festival of the Jews, so called because it was celebrated on the fiftieth day after the 16th of Nisan, which was the second day of the passover. The Hebrews called it the "feast of weeks," because it was kept seven weeks after the passover. They then offered the first fruits of the wheat harvest; besides which, they presented at the temple seven lambs of that year, one calf, and two rams, for a burnt-offering, two lambs for a peace-offering, and a goat for a sin-offering. The feast of Pentecost was instituted amongst the Israelites, first, to oblige them to repair to the temple of the Lord, in order to acknowledge his absolute dominion over the whole country, and to offer him the first-fruits of their harvest; and, secondly, that they might call to mind, and give thanks to God, for the law which he had given them from Mount Sinai, on the fiftieth day after their coming out of Egypt.

PENTECOSTE, or Whitsunday Island, a small island in the Southern Pacific Ocean, and one of the great archipelago of the New Hebrides, discovered by Bougainville in 1768.

PENTHESILEA, queen of the Amazons, succeeded Orythia, and gave conspicuous proofs of her courage at the siege of Troy, where she was killed by Achilles. Pliny says that she invented the battle-axe.

PENTLAND or Pictland Frith is a narrow strait of six miles in breadth, between the mainland of Scotland and the Orkney Isles.

PENULA, amongst the ancient Romans, was a coarse garment or cloak worn in cold or in rainy weather. It was shorter than the *lacerna*, and therefore more proper for travellers. It was generally brown, and succeeded the *toga* after the state became monarchical. Augustus abolished the custom of wearing the penula over the toga, considering it as too effeminate for Romans; and the ædiles had orders to suffer none to appear in the circus or forum with the lacerna or penula. Writers are not agreed as to the precise difference between these two articles of dress; but we are told that they were chiefly worn by the lower orders of the people.

PENULTIMA, or Penultimate Syllable, in *Grammar*, denotes the last syllable but one of a word; and hence the antepenultimate syllable is the last but two, or that immediately before the penultimate.

PENUMBRA, in *Astronomy*, a partial shade observed between the perfect shadow and the full light in an eclipse. It arises from the magnitude of the sun's body. For were he only a luminous point, the shadow would be all perfect; but, by reason of the diameter of the sun, it happens that a place which is not illuminated by the whole of the sun does yet receive rays from a part of that body.

PENZANCE, a seaport and market-town of Cornwall, in the parish of Madron and hundred of Penwith, 289 miles from London, and a few from the Land's End. It has a tolerable harbour, which, however, is dry at low water. It is in a district which abounds in minerals, chiefly lead, tin, and copper, with some silver. Mining operations form the chief occupation of the inhabitants. It has a market on Saturday, which is well and cheaply supplied. In virtue of the municipal corporation reform law, passed in 1835, the town annually elects the corporation, consisting of a mayor, six aldermen, and eighteen councillors; and for this purpose it is divided into two wards. The population amounted in 1801 to 3382, in 1811 to 4022, in 1821 to 5224, and in 1831 to 6563.

PEOR, a famous mountain beyond Jordan, which Eusebius places between Heshbon and Livias. The mountains Nebo, Pisgah, and Peor, were near one another, and probably formed parts of the same chain or ridge. It is very likely that Peor took its name from some deity of the same name, which was worshipped there; for Peor, Phegor, or Baal-peor, was known in this country.

PEPLUS was a long robe worn by the women in ancient times. It had no sleeves, reached down to the feet, and was so very fine, that the shape of the body might be seen through it. The Athenians used much ceremony in making the peplus, and in dressing with it the statue of Minerva. Homer makes frequent mention of the peplus of that goddess.

PEPONG, two small islands in the Eastern Seas, near the coast of China. Long. 107. E. Lat. 23. 22. N.

PEPPER, Piper, in *Natural History*, an aromatic berry of a hot quality, and chiefly used in seasoning. We have three kinds of pepper which are at present used in the shops; the black, the white, and the long pepper. Black pepper is the fruit of the *piper*, and is brought from the Dutch settlements in the East Indies. The common white pepper is factitious, being prepared from the black in the following manner. The latter is steeped in sea-water, and then exposed to the heat of the sun for several days, till the rind or outer bark loosens; it is then taken out, and, when it is half dry, rubbed till the rind fall off; the white fruit is next dried, and, lastly, the remains of the rind are blown away like chaff. A great deal of the heat of the pepper is taken off by this process, so that the white kind is fitter for many purposes than the black. However, there is a sort of native white pepper produced upon a species of the same plant, which is much better than the factitious, and indeed little inferior to the black. The long pepper is a dried fruit, of an inch or an inch and a half in length, and about the thickness of a large goose-quill. It is of a brownish-gray colour, and cylindrical in figure, and is said to be produced on a plant of the same genus.

PEPPER Bay, on the west coast of the island of Java, is situated thirty miles south-south-west of Bantam. Long. 105. 40. E. Lat. 6. 24. S.

PEPPERBERG, a town of the island of Java, on the southern coast, seventy-five miles south of Batavia.

PERA, or Pulo Pera, a small island in the Eastern Seas, situated at the entrance of the Straits of Malacca. Long. 98. 36. E. Lat. 5. 54. N.

PERAMBAUCAM, a town of the south of India, in the province of the Carnatic, memorable for the defeat and destruction of Colonel Baillie's force, in September 1780, by Hyder Ali. It is fourteen miles north-east of Conjeveram.

PERAMBULATOR, in surveying, an instrument for measuring distances, and called also odometer, pedometer, way-wiser, and surveying-wheel.

PERCEPTION is a word so well understood that it is difficult for the lexicographer to define it. It has been called the first and most simple act of the mind, by which it becomes conscious of its own ideas. This definition, however, is improper, as it confounds perception with consciousness; although the objects of the former faculty are things without us, and those of the latter the energies of our own minds. Perception is that power or faculty by which, through the medium of the senses, we become cognizant of objects distinct and separate from ourselves, and learn that we are but a small part in the system of nature. See Metaphysics.

PERCH, in land-measuring, a rod or pole of sixteen feet and a half in length. Of these rods, forty in length and four in breadth make an acre of ground. But, by the customs of several counties, there is a difference in this measure. In Staffordshire the perch is twenty-four feet; in the forest of Sherwood it is twenty-five feet, the foot being there eighteen inches long; and in Herefordshire the perch of ditching is twenty-one feet, the perch of walling sixteen and a half feet, and a pole of denshiered ground is twelve feet.

PERCH, a fish. See the article Ichthyology.

PERCOLATION, a chemical operation, which is otherwise denominated filtration.

PERCUSSION, in *Mechanics*, is the impression a body makes in falling or striking upon another, or the shock of two bodies in motion. See Dynamics and Mechanics.

PERCY Isles, a chain of islands in the South Pacific Ocean, distant about thirty miles from the north-east coast of New Holland, and extending from about 21. 32. to 21. 45. S. lat. The name of Percy Islands was given them in 1802 by Captain Flinders, who laid down their respective situations and bearings. The largest island is about thirteen miles in circumference. Turtle abound in these islands, which are visited by the Indians for the purpose of catching them. The large vampyre bat is frequently found here, hanging by the claws with its head downwards.

PEREASLAWL, a city of Russia, in the government of Poltawa, the capital of the circle of the same name. It is at the junction of the rivers Alta and Tracbesh, and was at one period the seat of the ancient Russian princes, and afterwards the see of a bishop, with an extensive diocese. It is still surrounded with earthen walls, and has a cathedral, nine other churches, 1000 houses, and 8000 inhabitants. It is 902 miles from St Petersburg. Long. 31. 27. E. Lat. 50. 4. N.

PEREKOP, a Russian town and fortress at the entrance of the Crimea, to which it is the only practicable approach by land. The town consists of two rows of houses, which line the sides of the great road. Next to its importance as a defensive station, it is of consequence as being the residence of a commission charged with the administration of the salt lakes of the Crimea. It is a great thoroughfare during the summer, more than 20,000 loaded carts of salt passing through it for the supply of the south of Russia. The vast ditches, ramparts, and walls of this place have been recently put in good order. The population consists of Russians, Greeks, Armenians, and Tartars, and, many of the latter being migratory, is very fluctuating.

PERENNIALS, or Perennial Flowers, in *Botany*, a term applied to those plants the roots of which abide many years, whether they retain their leaves in winter or not. Those which retain their leaves are called *evergreens;* but such as cast their leaves are named *deciduous* or *perdifols*.

PERESLAW, a city of Russia, in the government of Vladimir, and the capital of a circle of its own name, is situated on the river Trubesch. It is an ancient place, the see of a bishop, whose diocese is very extensive. It contains 780 houses and seventy wooden booths, with 4380 inhabitants, who are manufacturers of cloth, of silk, and of linen, and have considerable trade with the Ukraine. It is 504 miles from St Petersburg. Long. 37. 32. 25. E. Lat. 55. 15. 30. N.

PERFECT, something to which nothing is wanting, or which has all the requisites of its nature and kind.

PERFECTION, the state or quality of a thing that is perfect. Perfection is divided, according to Chauvinus, into physical, moral, and metaphysical. *Physical* or natural perfection is that by which a thing has all its powers and faculties, and those too in full vigour; and all its parts, both principal and secondary, and those in their due proportion, constitution, and adjustment. In this sense man is commonly said to be perfect when he has a sound mind in a sound body. Physical perfection is by the schools frequently termed ἐνεργητικη, because a thing is enabled thereby to perform all its operations. *Moral* perfection is an eminent degree of virtue or moral goodness, to which men arrive by repeated acts of piety, beneficence, and self-restraint. This is usually subdivided into absolute or inherent, which is actually in him to whom we attribute it; and imputative, which exists in some other, and not in him to whom it is attributed. *Metaphysical*, transcendental, or essential perfection, is the possession of all the essential attributes, or of all the parts necessary to the integrity of a substance; or it is that by which a thing has or is provided with every thing belonging to its nature. This is either absolute, where all imperfection is excluded, as in the Deity, or *secundum quid*, that is, in its own kind, or relative.

PERFUME denotes either the volatile effluvia from any body affecting the organ of smell, or the substance emitting those effluvia; in which last sense the word is most commonly used. The use of perfumes was frequent amongst the Hebrews, and the orientals in general, before it was known to the Greeks and the Romans. In the time of Moses perfumes must have been known in Egypt, since he speaks of the art of the perfumer, and gives the composition of two kinds of perfumes, one of which was to be offered to the Lord upon the golden altar in the holy place, and the other was appointed for the anointing of the high priest and his sons, as also of the tabernacle, and all the vessels that were used in divine service. The Hebrews had likewise perfumes which they employed in the process of embalming their dead. The composition is not known, but it is certain that they generally made use of myrrh, aloes, and other strong astringent drugs, that served to prevent putrefaction (John, xix. 49). Besides the perfumes for these purposes, the Scripture mentions others which the Hebrews used on various occasions. The spouse in the Canticles commends the scent of the perfumes of her lover; and her lover in return says, that the scent of the perfumes of his spouse surpasses the most excellent odours. He names particularly the spikenard, the calamus, the cinnamon, the myrrh, and the aloes, as forming part of those perfumes. The voluptuous woman described by Solomon says that she had perfumed her bed with myrrh, aloes, and cinnamon. The epicures mentioned in the book of Wisdom encourage one another to the luxuriant use of odours and costly perfumes. Isaiah reproaches Judæa, which he describes as a spouse faithless to God, with being painted and perfumed to please strangers: "Thou wentest to the king with ointment, and didst increase thy perfumes." Ezekiel seems to accuse the Jews of having profaned the odours and perfumes, the use of which was reserved to sacred things, by applying them to their own use. Perfumes came afterwards to be very common amongst the Greeks and the Romans, especially those composed of musk, ambergris, and civet. The *nardus* and *malobathrum*, which were held in much estimation, were imported from Syria. The *unguentum nardinum* was variously prepared, and contained many ingredients. *Malobathrum* was an Indian plant. Perfumes were also used at sacrifices to regale the gods, at feasts to increase the pleasures of sensation, at funerals to overpower cadaverous smells and please the manes of the dead, and in the theatres to prevent the offensive effluvia or odour of a crowd from being perceived.

PERGAMO, a town of Asiatic Turkey, once a large capital, but now a place of very little importance. It is situated about fifteen miles from the mouth of the Gramalki. The inhabitants are chiefly Turks, though it has a church belonging to the Christians. Long. 27. E. Lat. 39. 11. N.

PERGAMUS, an ancient kingdom of Asia, formed out of the ruins of the empire of Alexander the Great. It commenced about the year 283 before our era. The first sovereign was one Philetærus, an eunuch, by birth a Paphlagonian, a man of mean descent, and in his youth a menial servant to Antigonus, one of Alexander's captains. He afterwards served Lysimachus, king of Macedonia and Thrace, who appointed him keeper of his treasures lodged in Pergamus. Whilst he held this employment, having fallen under the displeasure of Arsinoe, wife of Lysimachus, she found means to excite a quarrel between him and his master; upon which Philetærus seized on the castle of Pergamus, together with the treasures intrusted to his care, amounting to ninety thousand talents. At first he offered his service, together with his treasure, to Seleucus, the king of Syria; but both Seleucus and Lysimachus dying soon afterwards, he kept possession of the town and treasure until his death, which happened twenty years after his revolt from Lysimachus.

Philetærus left the city of Pergamus to his brother, or, according to some, to his brother's son, Eumenes the First, who, laying hold of the opportunity offered by the dissensions amongst the Seleucidæ, possessed himself of many strongholds in the province of Asia; and, having hired a body of Galatians, defeated Antiochus as he was returning from a victory gained over his brother Seleucus Callinicus. By this victory he obtained possession of the greater part of Asia. But he did not long enjoy his acquisitions; for he died next year of immoderate drinking, a vice to which he was greatly addicted.

Eumenes was succeeded by Attalus the First, nephew of Philetærus, who, on his accession, assumed the title of king of Pergamus. He defeated the Gauls, who seemed desirous of settling in his territory; and, according to Livy, he was the first of the Asiatic princes who refused to pay a contribution to these barbarians. When Seleucus Ceranus was engaged in other wars, he invaded his territories, and conquered all the provinces on the Anatolian side of the Taurus; but was soon driven out of his new acquisitions by Seleucus and his grandfather Achæus, who, entering into an alliance against him, deprived him of all his newly-acquired territories, and even besieged him in his capital. Upon this Attalus invited to his assistance the Gauls who had settled in Thrace; and with their help he not only obliged the enemy to raise the siege of Pergamus, but quickly recovered all the provinces he had lost. After this he invaded Ionia and the neighbouring provinces, where several cities voluntarily submitted to his sway. The Teians, Colophonians, and the inhabitants of Ægea and Lemnos, sent deputies declaring themselves ready to acknowledge him as their sovereign; and the Carsenes, on the other side of the river Lycus, opened their gates to him, having first expelled the governor placed over them by Achæus. Thence he advanced to Apia, and encamping on the banks of the river Megithus, received homage from the neighbouring nations. But here the Gauls, being frightened by an eclipse of the moon, refused to proceed farther; a circumstance which obliged Attalus to return to the Hellespont, where he allowed his allies to settle, giving them a large and fruitful territory, and promising that he would always assist and protect them to the utmost of his power.

Attalus having thus settled his affairs with equal honour and advantage to himself, entered into an alliance with the Romans, and afterwards joined them in their war against Philip, king of Macedonia. Here he had the command of the Rhodian fleet, with which he not only drove the Macedonians quite out of the Greek seas, but having landed his men, he, in conjunction with the Athenians, invaded Macedonia, and obliged Philip to raise the siege of Athens, which he had greatly distressed. For these services the Athenians not only heaped on him all the favours they could bestow, but called one of their tribes by his name; an honour which they had never before bestowed upon any foreigner.

Attalus now attempted to organise a general confederacy of the Greeks against Philip. But whilst he was haranguing the Bœotians with a view to this object, and exhorting them with great vehemence to enter into an alliance with the Romans against their common enemy, he fell down speechless. However, having somewhat recovered, he desired to be carried by sea from Thebes to Pergamus, where he died soon after his arrival, in the seventy-second year of his age and forty-third of his reign.

Attalus was succeeded by his eldest son Eumenes the Second. The latter was exceedingly attached to the Romans, insomuch that he refused the daughter of Antiochus the Great in marriage, lest he should thus be led into a quarrel with that people. He also gave intimation to the Roman senate of the transactions of Ariarathes, king of Cappadocia, who was making great preparations both by sea and land. Nor did Eumenes stop here; for when he saw the war about to break out between Antiochus and the Romans, he sent his brother Attalus to Rome in order to give information of the proceedings of Antiochus. The senate heaped honours both on Eumenes and his brother; and in the war which followed, they gave the command of their fleet to the king of Pergamus, in conjunction with C. Livius Salinator. The victory gained on this occasion was in a great measure owing to Eumenes, who boarded some of the enemy's ships in person, and during the whole action behaved with uncommon bravery. Some time afterwards, Eumenes, having entered the territories of Antiochus with a body of five thousand men, ravaged all the country about Thyatira, and returned with an immense booty. But in the mean time Antiochus invaded Pergamus in his turn, ravaged the whole country, and even laid siege to the capital. Attalus, the king's brother, held out with a handful of men, until the Achæans, who were in alliance with Eumenes, sent a thousand foot and a hundred horse to his assistance. As this small body of auxiliaries were all chosen men, and commanded by an experienced officer, they behaved with such bravery that the Syrians were obliged to raise the siege. At the battle of Magnesia, too, Eumenes behaved with the greatest bravery, not only sustaining the first attack of the enemy's elephants, but driving them back again upon their own troops; which threw the ranks in disorder, and gave the Romans an opportunity of giving them a total defeat, by attacking them opportunely with their horse. In consequence of this defeat, Antiochus was obliged to conclude a peace with the Romans on such terms as they pleased to prescribe; one of which was, that he should pay Eumenes four hundred talents, and a quantity of corn, in recompense for the damage he had done to that prince.

Soon after this Eumenes was engaged in a contest with Prusias, king of Bithynia, who made war upon him by the advice of Hannibal, the celebrated Carthaginian general. But Eumenes, being assisted by the Romans, defeated Prusias in an engagement by sea, and another by land; disasters which so disheartened him, that he was ready to accept of peace on any terms. However, before the treaty was concluded, Hannibal found means to draw into the confederacy Philip of Macedonia, who sent Philocles, an old and experienced officer, with a considerable body of troops, to join Prusias. Eumenes then sent his brother Attalus to Rome with a golden crown, worth fifteen thousand talents, to complain of Prusias for making war on the allies of the Roman people without any provocation. The senate accepted the present, and promised to adjust every thing to the satisfaction of their friend Eumenes, whom they looked upon as the most steady ally they could boast of in Asia. But in the mean time, Prusias, having ventured another sea-fight, gained a complete victory by a contrivance of Hannibal. The greatest part of the ships of Eumenes were burned, several were taken, and the others were so much shattered that they became quite unserviceable. The same year Prusias gained over Eumenes two remarkable victories by land, both of which were entirely owing to stratagems of Hannibal. But, whilst matters were thus going on to the disadvantage of Eumenes, the Romans interfered, and by their deputies not only put an end to the differences between the two kings, but prevailed on Prusias to betray Hannibal; upon which the illustrious fugitive poisoned himself.

Eumenes being thus freed from such a dangerous enemy, engaged in a new war with the kings of Cappadocia and Pontus, in which also he proved victorious. His friendship for the Romans he carried to such a degree of enthusiasm, that he went in person to Rome to inform them of the machinations of Perses king of Macedonia. He had before quarrelled with the Rhodians, who sent ambassadors to Rome to complain of him. But as the ambassadors happened to arrive whilst the king himself was present in the city, the Rhodian ambassadors could not obtain any hearing, and Eumenes was dismissed with new marks of favour. This journey, however, had almost proved fatal to him; for, on his return, as he was going to perform a sacrifice at Delphi, two assassins, sent by Perses, rolled down two great stones upon him as he entered the straits of the mountains. By one of these he was dangerously wounded on the head, and by the other he received a contusion on the shoulder. In consequence of the blows, he fell from a steep place, and thus received so many other bruises, that when he was carried on board his ship it could not well be known whether he was dead or alive. His people, however, finding that he was still alive, conveyed him to Corinth, and from Corinth to Ægina, having caused their vessels to be carried over the isthmus.

Eumenes remained at Ægina till his wounds were cured, which was done with so great secrecy, that a report of his death was spread all over Asia, and even believed at Rome; nay, his brother Attalus was so convinced of the truth of this report, that he not only assumed the government, but even married Stratonice the wife of Eumenes. But in a short time Eumenes convinced both parties of his being alive, by returning to his kingdom. On receiving this intelligence, Attalus resigned the sovereignty in great haste, and went to meet his brother, carrying a halberd, as one of his guards. Eumenes received both him and the queen with great tenderness; only it is said he whispered in his brother's ear when he first saw him, "Be in no haste to marry my wife again till you are sure I am dead."

The king joined the Romans in their war against Perses; but during the course of it he suddenly cooled in his affection towards those allies whom he had hitherto served with so much zeal, and that to such a degree that he admitted ambassadors from Perses, and offered to remain neutral if the latter would pay him a thousand talents, and, for fifteen hundred, to influence the Romans to grant him a safe and honourable peace. But these negociations were broken off, by reason of the distrust which these two kings had of each other. Eumenes would not trust Perses unless he paid him the money beforehand; whilst, on the other hand, Perses did not care to part with the money until Eumenes had first performed what he promised; neither could he be induced to pay the sum in question, though the king of Pergamus offered to give hostages for the due performance of his promise. These negociations were as long as possible concealed from the Romans; but they at length came to be known, after which the republic began to entertain no little jealousy of their old friend, and therefore heaped favours upon his brother Attalus. Eumenes had sent him to Rome to congratulate the senate on the happy issue of the war with Perses, not thinking that his own practices had been discovered. However, the senate, without taking any notice of their disaffection towards Eumenes, entertained Attalus with the greatest magnificence; then several of the senators who visited him proceeded to acquaint him with their suspicions of the king, and desired Attalus to treat with them in his own name, assuring him that the kingdom of Pergamus would be granted him by the senate if he demanded it. Eumenes, alarmed at these proceedings, resolved to proceed in person to Rome, in order to justify himself. But the senate having already condemned him in their own minds, resolved not to hear his vindication, and made an act that no king should be permitted to enter the gates of Rome. Eumenes, who knew nothing of this, set forward on his journey, and landed at Brundusium; but no sooner did the Roman senate receive intelligence of his arrival, than they sent a quæstor to acquaint him with the decree of the senate, and at the same time to apprise him, that if he had any business to transact with the senate, he was appointed to hear it, and transmit it to them, but if not, that the king must leave Italy without delay. To this Eumenes replied, that he had no business of any consequence to transact, and that he did not stand in need of any of their assistance; and, without saying a word more, went on board his ship, and returned to Pergamus. On his return, the Gauls, encouraged by the cold reception which he had met with at Rome, invaded his territories, but were repulsed with great loss. This produced new complaints at Rome, and Eumenes was accused of keeping up a secret correspondence with the king of Macedonia; and the senators having conceived the most implacable hatred against him, seemed absolutely bent on his destruction, when he died, in the thirty-ninth year of his reign, leaving his kingdom and his wife to his brother Attalus.

Attalus, in the commencement of his reign, found himself greatly distressed by Prusias king of Bithynia, who not only overthrew him in a pitched battle, but advanced to the very walls of Pergamus, ravaging the country as he marched along, and at last reduced the royal city itself. The king, however, saved himself by a timely flight, and despatched ambassadors to Rome, complaining of the conduct of Prusias. The latter endeavoured to defend himself, and to throw the blame on Attalus. But, after a proper inquiry was made into the matter, Prusias was found to be entirely in the wrong, and was at last obliged to conclude a peace with his adversary upon the following terms, viz. that he should immediately deliver up to Attalus twenty ships with decks; that he should pay five hundred talents to Attalus within the space of twenty years; that he should pay a hundred talents to some of the other Asiatic nations, by way of reparation for the damages they had sustained from him; and that both parties should be content with what they had possessed before the beginning of the war. The last enterprise in which we find Attalus engaged was against Andriseus, the pretended son of Perses, king of Macedonia, in which he assisted the Romans. After this he gave himself up to ease and luxury, committing state affairs entirely to his ministers; and thus continued till his death, which happened in the eighty-second year of his age, and about 138 years before our era.

Attalus the Second was succeeded by Attalus the Third, the son of Eumenes; for the late king, considering that he only held the crown as a trust for his nephew, passed by his own children in order to give it to him, though he appears to have been by no means worthy of it. He is said to have been deprived of his senses through the violence of his grief for his mother's death; and, indeed, throughout his whole reign, he behaved more like a madman than a person of sane mind. On the death of this tyrant, a will was found, by which he left the Roman people heirs of all his goods; upon which they seized on the kingdom, and reduced it to a province of their empire by the name of Asia Proper. But Aristonicus, a son of Eumenes by an Ephesian courtesan, reckoning himself the lawful heir to the crown, and being by no means satisfied with this usurpation of the Romans, assembled a considerable army in order to maintain his pretensions. The people in general, having been accustomed to a monarchy, dreaded a republican form of government; and having, in consequence, assisted Aristonicus, they soon put him in a condition to reduce the whole kingdom to obedience. The news, however, were speedily carried to Rome; and Licinius Crassus, the pontifex maximus, was sent into the East, with orders to enforce submission to the king's will. Historians take no notice of any forces which were sent along with this commander; from which it is supposed, that he depended on assistance from the Asiatics, who were in alliance with Rome, or from the Egyptians. But when he went thither, he found both the Syrians and Egyptians so reduced that he could not expect any assistance from them. However, he was soon supplied with troops by the kings of Pontus, Bithynia, Cappadocia, and Paphlagonia; but he managed matters so ill that he was entirely defeated and taken prisoner. Those who took him designed to carry him to Aristonicus; but Crassus, not being able to endure the disgrace, would have laid violent hands on himself if he had not been disarmed.

Aristonicus did not long enjoy the fruits of his victory. Indeed he behaved very improperly after it; for, instead of preparing to oppose the next army, which he might have been assured the Romans would send against him, he spent his time in feasting and revelling. But he was soon roused out of his lethargy by Perpenna, the new consul, who having assembled with incredible expedition the troops of the allies, came unexpectedly upon him, obliged him to venture an engagement at a disadvantage, and entirely defeated him. Aristonicus fled to a city called

Stratonice, but was so closely pursued by the conqueror, that the garrison, having no means of supplying themselves with provisions, delivered up their leader, as well as a philosopher named Blosius, who had been the companion and counsellor of Aristonicus. The philosopher behaved with great resolution after being taken, and openly defended his siding with Aristonicus, because he thought his cause just. He exhorted the latter to prevent the disgrace and misery of captivity by a voluntary death; but Aristonicus, looking upon death as a greater misery than any captivity, suffered himself to be treated as his conquerors pleased.

In the mean time, a new consul, named Manius Aquilius, having arrived from Rome, sent a haughty message to Perpenna, requiring him immediately to deliver up Aristonicus as a captive belonging to his triumph when the war should be ended. With this demand Perpenna refused to comply, and his refusal had almost produced a civil war; but this was prevented by the death of Perpenna, which happened soon after the dispute commenced. The Pergamenians, notwithstanding the defeat and captivity of their leader, still held out with such obstinacy, that Aquilius was obliged to besiege, and take by force, almost every city in the kingdom. At last, however, the whole country being reduced, Aquilius triumphed, and the unhappy Aristonicus, being led in chains before his chariot, probably ended his miserable life in a dungeon.

PERGINE, a large but scattered market-town in the Austrian province of Tyrol, and the circle of Trent. It has some cloth manufactures; and near to it there are ironworks. The inhabitants amount to from 7000 to 8000.

PERIAGOGE, in *Rhetoric*, is used where many things are accumulated into one period, which might have been divided into several.

PERIANDER, one of those generally known as the seven wise men of Greece, was the son of Cypselus, tyrant of Corinth. He was born B. C. 665, and died at the age of eighty, B. C. 585. He succeeded his father in the government of Corinth, B. C. 625, and was distinguished at first for the mildness of his disposition; but yielding to the advice given him by Thrasybulus, prince of Miletus, he is said to have become a cruel tyrant. He married Lyside, whom he called Melissa, daughter of Procles, tyrant of Epidaurus, and of Eristheneia, daughter of Aristocrates, the celebrated king of the Arcadians. By her he had two sons, Cypselus and Locophron, the former of whom was an idiot. He struck his wife in a passion, and killed her, at the same time banishing Lycophron to the island of Corcyra, because he dared to bewail the fate of his mother (Herodot. v. 92, iii. 50). In the war between the Athenians and Mytilenæans, B. C. 606, he is said, according to one statement (v. 94, 95), to have been a mediator between the contending parties; but Strabo represents him as having assisted Pittacus. When he began to feel old age advancing, he sent for his son Lycophron; but the inhabitants of Corcyra put him to death, and when Periander failed in inflicting punishment on the authors of this calamity to him, he died of grief. Periander was the author of maxims for the guidance of human life, extending to two thousand hexameter verses. Laertius quotes two letters under the name of Periander, but there seems no good reason for believing that they are genuine. The cruel conduct of Periander made many of the ancients doubt whether the tyrant of Corinth ought to be considered as one of the wise men. It is to be observed, however, that there was a Periander of Ambracia, to whom some give this title. (Diogenes Laertius, *Life of Periander.*)

PERIANTHIUM, from περι, *round*, and ἀνθος, *a flower*, the flower-cup properly so called, or the most common species of calyx, placed immediately under the flower, which is contained in it as in a cup.

PERIAPATAM, a town of the south of India, in the province of Mysore, and towards the borders of the Coorg country. It is the city and domain of an ancient Polygar chief, who was conquered nearly two centuries ago by one of the rajahs of Mysore. The town and fort, and the surrounding country, were laid waste by orders of Tippoo Sultan, when the British army was approaching to it in 1790. In 1799 a battle was fought near this place, between General Stuart's forces and those of Tippoo, in which the latter were totally defeated, and the road to Seringapatam laid open to the victorious army. This district produces about 2000 weight annually of sandal wood, which is conveyed in great quantities to Tellicherry, and thence to China and Nubia. Under the mild government of its present rajah it is recovering from the desolation to which it was exposed. Long. 76. 25. E. Lat. 12. 20. N.

PERICARDIUM, in *Anatomy*, is a membranous bag filled with water, which contains the heart in man and in many other animals. (See ANATOMY.)

PERICARPIUM, from περι, *round*, and καρπος, *fruit*, the seed-vessel, or that organ of a plant which contains the seeds it discharges when ripe. The seed-vessel is in fact the developed seed-bud, and may very properly be compared to the fecundated ovary in animals; for it does not exist till after the fertilizing of the seeds by the male dust, and the consequent fall of the flower. All plants, however, are not furnished with a seed-vessel; and in such as are deprived of it, the receptacle or calyx performs its functions by enclosing the seeds as in a matrix, and accompanying them to perfect maturity.

PERICHORUS, in *Antiquity*, a name applied by the Greeks to their profane games or combats, that is, to such as were not consecrated to any of the gods.

PERICLES, one of the most celebrated of the Greek statesmen, was a native of Athens, and descended, both by the father and mother's side, from the most distinguished families of that city. His father Zanthippus had been concerned in the prosecution of the great Miltiades, and commanded the fleet which defeated the Persians at Mycale, B. C. 479. He married Agariste, the niece of Cleisthenes, the chief of the noble family of the Alcmæonidæ, and the leader of the party which had expelled the Pisistratidæ. It is not known in what year Pericles was born; but as he began to take part in public affairs about B. C. 469, it could scarcely be later than B. C. 490. He died in the autumn of B. C. 431, in the third year of the Peloponnesian war. He studied under the ablest masters that Athens could then furnish. Anaxagoras of Clazomenæ, whose force of understanding and extent of knowledge had acquired him the appellation of Intellect (νους), was the philosopher to whom he was chiefly indebted for the cultivation of his mental powers; but he also derived instruction from Zeno, the founder of the Eleatic school of philosophy, and from Damon, who, professing only music, was considered as the ablest speculative politician that Athens then produced. It is said that the young Pericles resembled much, both in person and voice, the tyrant Pisistratus, and this prevented him for some time from taking any part in public business. But when Aristides was dead, Themistocles banished, and Cimon employed in distant military expeditions, Pericles ventured to make his appearance before the people about B. C. 469; and his eloquence soon enabled him to acquire great influence over them. Although his inclination and feelings might have led him to unite himself to the aristocratical party, his interest and his peculiar talents made him solicit the favour of the people, and he became in course of time the leader of the popular faction. He concurred in the policy of his party in procuring, B. C. 461, the banishment of Cimon; and he also exerted himself to reduce the dignity of the Areiopagus, one of those measures which proved in the end fatal to the Athenian constitution, as it tended to leave the power of the democracy without control.

The increased expenses of the government rendered it necessary that some means should be adopted to improve the income of the state. Pericles proposed that the common treasury of the confederacy, at the head of which Athens stood, should be removed from Delos to Athens. This fund was intended to provide the means of defence against any attack on Greece by a foreign enemy, more particularly by the Persians; and a small yearly assessment was made on each of the confederate states for this purpose. By the will of the Athenians this assessment was increased; and it was determined that the tribunals of Athens should decide all disputes which might arise respecting it. These measures were by no means fair, but the supremacy of Athens by sea made any opposition to its demands at present hopeless. Pericles took part in all the proceedings of his party, although he had not yet acquired the chief control in the state. He was present at the battle of Tanagra, B. C. 457, and distinguished himself the more as he had insisted that Cimon, who had offered his services, should not be allowed to be present on the occasion. The Athenians, however, were defeated, and obliged to retire. In their distress they began to turn their eyes towards Cimon, and it seems to have been thought advisable by the popular party that he should be recalled. Pericles himself moved the decree, B. C. 456, and Cimon returned to Athens, after the expiration of only five years of the term of his banishment. On the death of Cimon in Cyprus, B. C. 449, Pericles was left nearly without a rival; and the nobility thought it necessary that they should bring forward some one to oppose his monopoly of power. Thucydides, son of Melesias, brother-in-law of Cimon, was the person to whom they looked; and, by his abilities, his rank, and his conduct through life, he was certainly entitled to high consideration. The two parties now gradually separated; and they never afterwards coalesced, as they had done under Cimon. A war of words was carried on; but we have little account of it, except the anecdote in which Thucydides candidly acknowledges the superiority of his rival: "When I wrestle with Pericles," he said, "if I throw him ever so decidedly, he can persuade the spectators that he threw me."

It was about this time that some Bœotians, who had been driven from their country in consequence of the Athenian conquest, contrived to get possession of Orchomenos, Chæroneia, and some other towns in that neighbourhood. The Athenian army under Tolmides easily dispossessed them, but on its return it was attacked by another party of exiles at Coronea, B. C. 447, and entirely defeated, with the death of the general. The revolt of Eubœa was the immediate consequence of this defeat; and an army under Pericles had scarcely landed upon the island, when intelligence reached him that the adverse party in Megara had risen, and, with the assistance of Corinth, had overpowered the Athenian garrison, and driven it out of the city. Rumours of an intended invasion of Attica by the Spartans were likewise brought to him. Pericles led back his army from Eubœa, defeated the Megareans, and compelled them to confine themselves within the walls of their city. The attack of the Spartans did not take place till the following spring, and Pericles was believed to have succeeded in bribing the Spartan general Cleandrides to withdraw his troops, as he retreated without striking a blow. Pericles then returned to Eubœa, and the whole island was quickly reduced. The insecure tenure of the Athenian power induced the leading men to seek an accommodation with Sparta, even on conditions that were highly disadvantageous. They had already lost Bœotia, and they now agreed to give up all pretensions to Megara and its territory, to withdraw their garrisons from Trœzen in Argolis, and to afford no assistance whatever to the democratical party in Achaia. On these conditions, a truce for thirty years was concluded, B. C. 445, between the two states. The two parties in Athens were now left at liberty to contend with each other; and as neither was willing to concede any thing to its rival, matters soon came to a crisis, and Pericles succeeded in procuring the banishment, B. C. 444, of Thucydides, by ostracism. From that moment Pericles became the master of Athens and all her dependencies.

The administration of Pericles lasted for fifteen years; and though the seeds of future evils were then plentifully sown, it was a period during which arts, science, and taste reached a perfection which no country has ever surpassed. The policy, not less than the inclination, of Pericles, led him to encourage them, as he found it easier to direct the will and caprices of the sovereign people whilst he excited their admiration by the magnificence of his undertakings. Nothing seems more wonderful than the expedition with which works of stupendous magnitude, and of inimitable beauty, were completed. Many edifices, each of which might have required the labour of many successive ages, were finished during the administration of one prosperous man. The celebrated Phidias was the superintendent to whose taste and skill the whole management was intrusted; and the perfection of design, and even of workmanship, can still be appreciated from the reliques, after a lapse of more than two thousand years. The Parthenon was erected under his eye; and it is by no means unlikely that we may still possess many of his designs in the bas-reliefs which have been transferred from that temple, and now form the most valuable part of the British Museum. Whilst Phidias was employed in executing works of sculpture, Zeuxis and Parrhasius were not less eminent in painting; and Æschylus, Sophocles, and Euripides were calling forth the plaudits of the Athenians by those tragedies which still equally excite our admiration. To this love of the fine arts Pericles added eloquence, such as was fitted to control the passions of a multitude, and an assiduity in public business which never flagged. His integrity, too, was never once called in question; and though he had unlimited control over the public revenues for so long a period, at his death it was found that his private property was even less than when he had received it from his father. Although he was the constant object of satire to the comic poets, and both his person and administration were daily attacked with the severest invectives, he stood firm in the affections of the people, who appear to have never for a moment wavered. It was the chief object of his policy to keep the people either amused or employed; and for this purpose he sent out during peace a squadron of sixty galleys, to exercise for eight months every year. He got rid of the more restless citizens by sending them to various colonies; and it was under his direction that the colony of Thurium, in the south of Italy, was settled, B. C. 443, whither went Herodotus and the orator Lysias.

The first interruption of the peace arose from a dispute between two Asiatic states of the Athenian confederacy, Samos and Miletus, who each claimed the sovereignty over Priene, and it was found impossible to settle the dispute without having recourse to arms. Miletus finding itself worsted, applied to the Athenians for assistance, which Pericles thought proper to grant. His enemies asserted that he was induced to come to this decision by a wish to gratify his mistress Aspasia, a native of Miletus, and one of the most celebrated women of ancient times. (See ASPASIA.) There are sufficient reasons assigned, however, why the Athenians should have interfered, without supposing that Pericles was swayed by any thing but a regard for the interests of his country. He led a considerable fleet, B. C. 440, against the Samians; and, after a nine months' siege, they were compelled to capitulate. Pericles returned with increased popularity, and gained much applause from the eloquence with which he pronounced the funeral oration over those who had fallen in battle. The historian Thucydides does not mention what part Pericles took in those measures which eventually led to the Peloponnesian war; but Plutarch asserts that he was the sole author of that contest. It is said that the people were beginning to show some symptoms of dissatisfaction with his sway, and were listening readily to all accusations against his friends. Phidias had been thrown into prison, and had there died, not without suspicion of poison. Aspasia had been accused and acquitted only through the great exertions of Pericles; and he had found it necessary to recommend to his friend Anaxagoras to retire from Athens for a time, as he was not certain that he could protect him from the malice of his enemies. He knew that upon any critical emergency they must have recourse to him; and, to withdraw the attention of the people from himself and friends, it is said he used every means to fan the flame of war, and to prevent all possibility of an arrangement between the Spartans and Athenians. When war at last was determined on, B. C. 431, Pericles took the whole direction of it on himself, and, thinking it hazardous to venture a battle against the united forces of the Peloponnesians, kept the Athenians within the fortifications of the city. The crowded state of the city, from the peasants who had fled before the enemy, and an insufficiency of food, were the main causes probably of that pestilential disease which broke out with such violence in Athens during the second year of the war, and which is so graphically described by the historian Thucydides (ii.). The Athenians now lost all patience, and wreaked their vengeance upon Pericles, by imposing a fine of fifteen talents on him. At the same time that his influence with the people was thus diminished, he was suffering much from the calamities which had befallen many of his relations, and from a misunderstanding which had for some time prevailed in his own family. He had originally married one of his own relations, but as their dispositions were by no means suited to each other, they had separated, after having two sons, Xanthippus and Paralus. Pericles then lived with Aspasia, towards whom he bore the tenderest regard. Xanthippus was naturally extravagant, and had married a young and expensive wife, who was unwilling to brook the frugality of her father-in-law. They lived therefore in a constant state of irritation with Pericles, and took every opportunity of annoying him. Xanthippus was carried off by the plague, as well as many other of his relations. Pericles bore up against all his misfortunes until the death of Paralus, his last surviving legitimate son, which completely subdued his unbending spirit, and he gave up all attention to public business. It was soon found, however, that no one was capable of filling his place, and the people again solicited Pericles to re-assume the reins of government. To this he acceded; and one of the first favours that he asked was, that they would allow him to enrol a natural son in his tribe, and thereby make him legitimate. In compassion for his misfortunes this was granted, and his son, Pericles, was afterwards one of the ten commanders in the naval engagement of Arginusæ. Pericles was soon after this seized with the plague, and died in the year 428 B. C. to the great regret of the Athenians. He is said to have left nothing in writing, except some public decrees. (Thucydides, *Peloponnesian War;* Plutarch, *Life of Pericles.*)

PERIGEE, in *Astronomy*, that point of the sun or the moon's orbit in which they are at the least distance from the earth. In this sense it is opposed to apogee.

PERIGRAPHE, a word usually understood to express a careless or inaccurate delineation of any thing; but in Vesalius it is used to express the white lines or impressions that appear on the musculus rectus of the abdomen.

PERIGUEUX, an arrondissement of the department of the Dordogne, in France, 775 square miles in extent. It comprehends nine cantons, divided into 126 communes, and contains 91,000 inhabitants. The capital is the city of the same name, which is also the seat of the civil, military, and judicial governments of the department. It stands on the right bank of the river Isle, and is fortified. The streets are narrow and crooked, and the houses old and lofty, so that its appearance is gloomy. It is the see of a bishop, contains 1150 houses, with 8600 inhabitants, and has a public library of 14,000 volumes, a fine old cathedral, and the ruins of a Roman amphitheatre, with some other ancient remains. Long. 0. 37. 56. E. Lat. 45. 11. 10. N.

PERIHELIUM, in *Astronomy*, that part of the orbit of a planet or comet in which it is at its least distance from the sun. In this sense it is in opposition to aphelium.

PERIM, a small island in the Straits of Babelmandeb, destitute of fresh water. It has a good harbour, and is about four miles distant from the coast of Africa. Long. 43. 50. E. Lat. 12. 36. N.

PERIMETER, in *Geometry*, the bounds or limits of any figure or body. The perimeters of surfaces or figures are lines, and those of bodies are surfaces. In circular figures, instead of perimeter, we say circumference or periphery.

PERINDA, a considerable town of Hindustan, in the province of Dowletabad. It is the capital of a district of the same name, has a strong citadel or fort, and belongs to the Mahrattas. Long. 76. 50. E. Lat. 18. 33. N.

PERINGARY, a town of Hindustan, in the Southern Carnatic, and district of Marawas, thirty-two miles east-south-east from Madura. Long. 73. 40. E. Lat. 9. 38. N.

PERINRAPAX, one of the Laccadive Islands, in the Indian Sea. Long. 71. 18. E. Lat. 11. 10. N.

PERIOD, in *Astronomy*, the time occupied by a star or planet in making a revolution round the sun, or the duration of its course till it return to the same part of its orbit. See ASTRONOMY.

PERIOD, in *Music*. See the article MUSIC.

PERIOD, in *Chronology*, denotes a revolution of a certain number of years, or a series of years, by which, in different nations, and on different occasions, time is measured. See CHRONOLOGY.

PERIOD, in *Grammar*, denotes a small compass of discourse, containing a perfect sentence, and distinguished at the end by a point or full stop. Father Buffier observes that there are two difficulties in the use of the period or point; first, in distinguishing it from the colon or double point; and, secondly, in determining justly the end of a period or perfect sentence. It may be remarked, that the supernumerary members of a period, separated from the rest by colons and semicolons, usually commence with a conjunction; yet it is true that sometimes these conjunctions rather begin new periods than supernumerary members of a preceding one. It is the sense of things, and the author's own discretion, that must make the proper distinction in such cases. No rules will be of any service unless this be admitted as one, that when that which follows the conjunction is of as great extent as that which precedes it, it is usually a new period, but otherwise not. The second difficulty arises from this, that the sense appears to be perfect in several short detached phrases, in which it does not seem there should be periods. This is frequent in free discourse, as, *We are all in suspense, make your proposals immediately, you will be to blame for detaining us longer.* Here it is evident that simple phrases have each a perfect sense like periods, and ought to be marked accordingly; but that the shortness of the discourse making them easily comprehended, the pointing is neglected. De Colonia defines a period a short but perfect sentence, consisting of certain parts or members depending one upon another, and connected together by some common vinculum. According to the celebrated definition of Aristotle, a period is a discourse which has a beginning, a middle, and an end, all of them visible at one view. Rhetoricians, in treating of the structure of sentences, consider a period as one of the four parts of composition. The periods allowed in oratory are three: a period of two members, called by the Greeks *dicolos*, and by the Latins *bimembris;* a period of three members, called *tricolos* and *trimembris;* and a period of four, called *quadrimembris* and *tetracolos*.

Period, in numbers, is a distinction made by a point or comma, after every sixth place or figure, and used in numeration for the more readily distinguishing and naming of the several figures or places.

Period, in *Medicine*, is applied to certain diseases which have intervals and returns, to denote an entire course or cycle of such disease, or its progress from any state through all the rest, till it return to the same again.

PERIODIC, or Periodical, something that terminates or comprehends a period; as a periodic month, or the space of time in which the moon completes her period.

PERIOECI (περιοικοι), in *Geography*, such inhabitants of the earth as have the same latitudes, but opposite longitudes, or live under the same parallel and the same meridian, but in different semicircles of that meridian, or in opposite points of the parallel. These have the same common seasons throughout the year, and the same phenomena of the heavenly bodies; but when it is noon-day with the one, it is midnight with the other, there being twenty-four hours in an east or west direction. These are found on the globe by the hour-index, or by turning the globe half round, that is, 180 degrees either way.

PERIPATETICS, philosophers, followers of Aristotle, and supporters of the peripatetic philosophy, called also *Aristotelians*. Cicero says that Plato left two excellent disciples, Xenocrates and Aristotle, who founded two sects, which only differed in name; the former took the appellation of *Academics*, being those who continued to hold their conferences in the Academy, as Plato had done before; the latter, who followed Aristotle, were called *Peripatetics*, from περιπατεω, *I walk*, because they disputed walking in the Lyceum. (See Aristotle and Aristotelian Philosophy.)

PERIPATON, in *Antiquity*, the name of that walk in the Lyceum where Aristotle taught, and whence the name of Peripatetics was applied to his followers.

PERIPETEIA, in the drama, is that part of a tragedy in which the action is turned, the plot unravelled, and the whole concludes.

PERIPHERY, in *Geometry*, the circumference of a circle, ellipsis, or any other regular curvilinear figure.

PERIPHRASIS, or circumlocution (formed from περι, *about*, and φραζω, *I speak*), in *Rhetoric*, a circuitous form of words, much affected by orators, to avoid common and trite modes of expression. The periphrasis is of great use on some occasions; and it is often necessary, to make things be conceived which it is not proper to name. It is sometimes polite to suppress the names, and only to intimate or allude to them. These turns of expression are also particularly serviceable in oratory; for the sublime admitting of no direct citations, there must be a compass taken to insinuate the authors whose authority is borrowed. A periphrasis, by turning round a proper name in order to make it understood, amplifies and raises the discourse; but care must be taken that it be not too much swelled, nor extended *mal à propos*, in which case it becomes flat and languid.

PERIPNEUMONY, Περιπνευμονια (formed from περι, *about*, and πνευμων, *lungs*), in *Medicine*, an inflammation of some part of the thorax, properly of the lungs, attended with an acute fever, and a difficulty of breathing.

PERIRPHANTERIUM, a vessel of stone or brass filled with holy water, with which all those were sprinkled who were admitted by the ancients to their sacrifices. Beyond this vessel no profane person was allowed to pass. We are told by some that it was placed in the *adytum*, or inmost recess of the temple; but others say that it was placed at the door, which indeed seems to be the most probable opinion. It was used both by Greeks and Romans, and has been evidently borrowed, like many other Pagan ceremonies, by the Church of Rome. The Hebrews had also a vessel for purification.

PERISCII, in *Geography*, the inhabitants of either frigid zone, between the polar circles and the poles, where the sun, when in the summer signs, moves only round about them, without setting; and consequently their shadows in the same day turn to all the points of the horizon.

PERISTALTIC, a vermicular spontaneous motion of the intestines, performed by the contraction of the circular and longitudinal fibres of which the fleshy coats of the intestines are composed; by means of which the chyle is driven into the orifices of the lacteal veins, and the fæces are protruded towards the anus.

PERISTYLE, in *Ancient Architecture*, a building encompassed with a row of columns on the inside.

PERITROCHIUM, in *Mechanics*, denotes a wheel or circle, concentric with the base of a cylinder, and moveable together with it round its axis.

PERJURY is defined by Sir Edward Coke to be a crime committed when a lawful oath is administered, in some judicial proceeding, to a person who swears wilfully, absolutely, and falsely, in a matter which is material to the issue or point in question. In ancient times it was in some places punished with death; at other periods it made the false swearer liable to the punishment due to the crime which he had charged the innocent person withal; and at others, again, it subjected him to a pecuniary fine. But though it escaped human, yet it was thought, amongst the ancients in general, that the divine vengeance would most certainly overtake it; and there are upon record many severe inflictions from the hand of God, as monuments of the abhorrence in which this atrocious crime is held by the Deity. The souls of the deceased were supposed to be employed in punishing perjured persons. Even the inanimate creation was thought to take vengeance on this crime. The Greeks supposed that no person could swear falsely by Styx without some remarkable punishment; and that any one guilty of perjury could not enter the cave of Palæmon at Corinth without being made a memorable example of divine justice. In Sicily, at the temple of the Palici, there were fountains called *Delli*, from which issued boiling water, with flames and balls of fire; and we are told that if any person swore falsely near them, he was instantly struck dumb, blind, lame, or dead, or was swallowed up by the waters. But although perjury was thus held in general abhorrence, yet in spite of the credit given to such accounts of divine inflictions, it was so much practised by the Greeks, that *Græca fides* became a proverb. Lovers' perjuries, however, were supposed to pass unnoticed, or to be but very slightly punished with blackness of the nails, a decayed tooth, or some similar diminution of beauty. The ancient philosophers were so afraid of perjury, that even an oath before a judge was never admitted excepting for want of other proof. Plato's precept was, not to administer an oath wantonly, but upon deep grounds, and with the strictest caution. Ulpian gives his opinion thus: "Some are forward to take oaths from a contempt of religion; others, from an extraordinary awe of the Divine Majesty, carry their fear to an unreasonable superstition, so as to make an equitable decision of a judge necessary." "No man will perjure himself," says Aristotle, "who apprehends vengeance from Heaven and disgrace amongst men." Clinias was so very scrupulous, that rather than take even a lawful oath, he suffered the loss of three talents. Perjury, in the time of Philo Judæus, was abominated and capitally punished amongst the Jews; but since that time they have much degenerated, being poisoned by the Talmud, which states, that he who breaks his promissory oath, or any vows he enters into during the year, if he have a mind that they should be ineffectual and invalid, may rise the last day of the year, and say, Whatever promises, oaths, and vows, I may think fit to make in the year following, let them be null, void, and of no effect.[1] The modern Jews employ the same artifice, thinking that they may thus lawfully deceive the Christians.

PERIZONIUS, James, one of the most learned philologists and most judicious critics whom Holland has produced, was born at Dam, in the province of Groningen, in the year 1651. His father, who was both pastor and rector of the school of that place, having, in 1664, been appointed professor of theology at Deventer, young Perizonius there began his studies under Gisbert Cuper, and afterwards went to pursue them at Leyden under George Grævius. Under these two able masters, his progress was extremely rapid; and the death of his father, who intended him as his successor in the chair of theology, leaving him at liberty to follow the bent of his inclinations, he applied himself with fresh ardour to the study of the ancient languages and of history. In the year 1674, he resumed his academical courses, which the war had interrupted, and, when he had completed them, he was appointed rector of the gymnasium at Delft. In 1681, he removed to the academy of Franeker, as professor of eloquence and history, which he taught with such distinction and success, that the curators of the academy, desirous to attach him to the school the reputation of which he had so ably supported, made several additions to his salary. Nevertheless, in 1693, Perizonius accepted the chair of history, eloquence, and the Greek language, in the university of Leyden; and to these subjects he, in 1702, added prelections on the history of the united provinces of the Low Countries. The lustre of his talents shone daily brighter and brighter; and although he discharged with exemplary diligence and fidelity his duty towards his pupils, he every year published some new production calculated to extend his reputation as a philologist. But his assiduous and uninterrupted labours at length undermined his health, which was naturally delicate, and, after languishing for some time in a hopeless condition, he died at Leyden on the 6th of April 1715. Perizonius, though a man of an amiable and obliging disposition, was nevertheless sensitive, and fond of disputation. He engaged in several keen controversies, particularly with Ulric Huber, professor of law at Franeker, on the sense of a passage in the Epistle of St Paul to the Philippians; with Francius, professor of eloquence at Amsterdam; with James Gronovius, on the death of Judas Iscariot; with John Leclerc, on the subject of Quintus Curtius; and with Kuster on the *æs grave* of the ancients. The works of Perizonius all display erudition, but are deficient in order and method. Besides good editions of various authors, he wrote, 1. Animadversiones Historicæ, in quibus quam plurima in priscis Romanarum rerum sed utriusque linguæ autoribus notantur, multa etiam illustrantur atque emendantur, Amsterdam, 1685, in 8vo; 2. Q. Curtius Rufus in integrum restitutus, vindicatus, Leyden, 1703, in 8vo; 3. De Doctrinæ Studiis, nuper post depulsam barbariem diligentissime denuo cultis et desideratis, nunc vero rursus neglectis fere et contemptis, Leyden, 1708, in 8vo; 4. Rerum per Europam sæculo XVI. maxime gestarum Commentarii Historici, *ibid.* 1710, in 8vo; 5. Origines Babylonicæ et Ægyptiacæ, Leyden, 1711, in two vols. 8vo, a work full of curious and interesting remarks on the chronology of Egypt, in opposition to Marsham, Usher, Capell, Pezron, and some other chronologists; 6. Opuscula Minora, Orationes atque Dissertationes varii et præstantioris argumenti, Leyden, 1740, in two vols. 8vo, preceded by a Life of Perizonius, and a catalogue of the manuscripts which he bequeathed to the library of Leyden. Amongst the works edited by this able scholar may be mentioned the History of Ælian, 1701, in two vols. 8vo, and the Minerva of Sanctius, 1714, in 8vo. (A.)

PERIZZITES, the ancient inhabitants of Palestine, who were mingled with the Canaanites. There is some probability that they themselves were Canaanites; but having no fixed habitations, being sometimes dispersed in one country and sometimes in another, they were for that reason called *Perizzites*, which signifies "scattered" or "dispersed." The Perizzites did not inhabit any certain portion of the land of Canaan; there were some of them on both sides of the river Jordan, in the mountains, and on the plains. In several places of Scripture the Canaanites and Perizzites are mentioned as the two principal tribes of the country.

PERM, a town and very extensive government of Russia. The province is situated chiefly in European, but partly also in Asiatic Russia, and is bounded by the government of Viatka on the west, and that of Tobolsk on the east. It has an area of 116,000 square miles, with a population of not more than 1,100,000. It is of a very diversified surface, being intersected from north to south by branches of the great Ural chain. The hills are covered with sand and impenetrable forests, which afford abundant shelter to wild animals, such as the bear, the wild boar, the wolf, foxes, and hares, and the sable and the marten, which are hunted over their farms. It is not a productive country; the summer is warm; but towards autumn, the chill air from the mountains often blights the produce of the harvest, and renders it necessary to import corn for the sustenance of the inhabitants. It has mines of copper, iron, and salt, which it exports to the annual amount of 2000 tons of copper and 10,000 tons of iron; cattle are also exported. The inhabitants are a mixed race, partly Russian and partly of Finnish and Tartar descent. They are principally occupied as shepherds; about 50,000 are employed in the mines. Perm is an inland province. The rivers by which it is intersected are far from the sea; those on the west side of the Ural Mountains flowing into the Kama, which joins the Wolga, and those on the east side falling mostly into the Oby, the outlet of which is the frozen ocean. The inhabitants are partly Christians, partly Mahommedans and Pagans. The town of Perm is situated on the river Kama. It has some neat public buildings, such as two churches, the government-offices, a public school, and an hospital; and carries on an extensive trade in the metals wrought in the surrounding country. The population is 3800. It is 910 miles south by east of St Petersburg, and 720 east-north-east of Moscow. Long. 56. 26. 30. E. Lat. 58. 1. 13. N.

PERMACOIL, a small town and fortress of the south of India, in the province of the Carnatic, situated on a rock from two to three hundred feet in height, but at its base not more than five hundred yards broad. It is exceedingly steep and difficult of access, but was taken by the British, in 1760, under Colonel Coote, who was wounded in the attack. It is seventy-two miles south-south-west from Madras, and twenty miles north-west from Pondicherry. Long. 79. 52. E. Lat. 12. 13. N.

PERMEABLE, a term applied to bodies of so loose a texture as to let something pass through them.

---

[1] Tract. iii. part 3, of the Talmud, in the treatise *Nedharim*, chap 4.

Pernambuco.

PERNAMBUCO, a large and important province of Brazil, in South America. It is separated on the south from the provinces of Seregipe and Bahia by the river St Francisco, and from Minas Geraes by the river Carinhenha; on the west it touches on Goyaz; and Paraiba, Seara, and Piauhy bound it on the north. This province is reckoned one of the most flourishing and important in Brazil, and contains more ports than any other, Recife, the capital, being only inferior to Rio and San Salvador in commercial enterprise and industry. Pernambuco extends about six hundred miles in length, but its breadth is much less, being only about fifty miles in the middle, though it widens to about two hundred towards each extremity. Its surface is very unequal, being in some parts mountainous, dry, and barren. In the interior, behind the capital, are immense plains, stretching to a great distance in all directions, although traversed in part by the great middle chain of mountains called the Serra of Borborema, which is described as the most majestic in Brazil. It commences near the sea, in the province of Rio Grande do Norte, and traverses that of Paraiba from north-east to south-west; it then bends to the west, separating that province from Pernambuco and Seara; and, lastly, inclines to the northward, dividing Pernambuco from Piauhy, its name changing as frequently as its altitude varies. In some parts it is rocky and barren, but the greater portion of it is covered with beautiful forests. The whole of this maritime district or canton was included, up to 1810, in the jurisdiction of the ouvidor of Jacobina; but it now goes by the name of the ouvidoria of the sertam of Pernambuco. The most important river of this state, or of any other in Brazil, belonging wholly to the country, is the St Francisco, the largest stream which flows into the Atlantic between the Amazons and the Plata. It rises in the serra of Canastra, in the province of Minas Geraes, in latitude 20° south. After traversing that province from south to north, it bends to the north-east on touching Pernambuco, and flowing along the borders of that state, keeps the same general bearing till within two hundred miles of the sea, when it bends to the south-west, entering the Atlantic in south latitude 11° nearly, after a course of more than one thousand miles. It receives several large streams during the first part of its course, the principal being the Carinhenha, which joins it on the borders of the comarca of Paracatu; the Rio das Velhas, and the Rio Verde, which enter from the right; and the Paracatu, Correntes, and Rio Grande, which flow into it from the left. But no stream of any importance joins the St Francisco after the confluence of the Rio Grande; and so few streams of any description flow from the arid regions of Bahia and Pernambuco, that it may be doubted whether it does not lose more water by evaporation than is supplied by all the paltry affluents which join it during the latter part of its course. After the confluence of the Rio Grande, it bends first to the east, then to the east-south-east, to the aldeia of Vargem Redonda, where the navigation from above terminates. Below Villa Nova the river begins to separate into two large portions, forming a great number of low wooded islands, which are covered by the inundations. This great river, so deep in the interior during the middle part of its course, at length discharges itself by two shallow mouths. The principal one, which is the most northerly, although nearly two miles in width, has not depth enough to allow of the entrance of sumacas, except at high water. In fact, it is navigated by larger boats in the upper than in the lower part of its course.

The climate of Pernambuco is hot and moist in the interior, but more agreeable in the maritime district. Generally speaking, the soil is in many parts rich and fertile, producing cotton, sugar, cocoa, maize, mandioc, and a variety of fruits, medicinal herbs, and vegetables. In the interior, the vast plains already mentioned are covered with luxuriant grass, upon which vast herds of cattle are fed; but these will be described afterwards. The province is divided into two parts by the river Pajehu, a tributary of the St Francisco, namely, the eastern and western districts or cantons. The eastern canton or ouvidoria is subdivided into three comarcas, the northern, central, and southern, the respective head towns of which are Olinda, Recife, and Alagoas. The western, however, has latterly been regarded as a separate province; but if so, it is a very small and unimportant one. The ouvidoria, as containing the capital, demands our first attention. Recife, or, as it is commonly called, Pernambuco, is not to be confounded with Olinda, although some geographers have considered them as forming but one city. It stands upon a flat, and is divided into three parts, a peninsula, an island, and the continent. Recife, or Pernambuco properly so called, is built upon a peninsula, which extends to the southward of Olinda. This is the most mercantile part of the threefold city. St Antonio stands upon an island or sand-bank formed by the arms of the Capibaribe, being connected with Recife by a large bridge almost entirely constructed of stone. The third division of the city is situated on the main land, to the southward of the other two, and is joined to them by a wooden bridge, considered as the largest in Brazil. This portion of Pernambuco is called Boa Vista, where the richer inhabitants reside. The appearance of the country, when Pernambuco is approached by sea, is described as charming. The hills are clothed with wood, gradually rising towards the interior, but none of them is of any considerable height. A singular reef of rocks runs parallel with the coast, and forms the harbour of Pernambuco, vessels being moored between it and the town, safe from every storm. This remarkable reef at the top is scarcely sixteen feet in breadth. To a great depth on the outside it slopes off more rapidly than the Plymouth breakwater, but it is perpendicular within, thus forming a magnificent natural bulwark or breakwater, within which the ocean is as still as a mill-pond. The reef extends beyond the northern boundary of the province to Maranham on the south. In some parts it sinks under water, and there are numberless breaks, by which a communication with the sea is laid open. In breadth it varies from a few fathoms to three quarters of a mile; but everywhere the water is of sufficient depth to admit the vessels mooring close to the rock. There is a bar at the entrance of the harbour, over which, in ordinary tides, there are sixteen feet of water, so that ships of considerable burden may lie there. The entrance into the harbour is very narrow, and close by a fort built on the reef. The hill of Olinda, studded with houses and convents, rises on the right hand, and an island thickly planted with cocoa-nut trees adds considerably to the scene on the left. The principal street of Boa Vista, the last portion of Pernambuco which remains to be described, is broad and handsome, although the ground on which it stands used formerly to be overflowed at high water. A long embankment connects the sand-bank and town of St Antonio with the mainland at Affogados, to the south and west of Boa Vista. The river Capibaribe, so famous in Pernambucan history, discharges its waters into the channel between St Antonio and Boa Vista, after running for some distance in a course nearly from east to west. The city of Pernambuco, which, Mr Southey remarks, "has not inaptly been called the Tripoli of the New World," has continued to be a place of the first consequence from the period of the Dutch conquest; and no other place has derived so great and unequivocal advantages from the growth of the cotton trade. Recife was built by the Dutch under Maurice of Nassau, and by them called Maurice Town or Mauritius. It is situated in latitude 8. 14. south, and longitude 35. 15. west, containing a population of above 60,000 souls. Of these, in 1821 not above a third were whites, and they must now be greatly diminished. The rest consisted of mulattoes and negroes. The former are, generally speaking, more active, more industrious, and much more lively, than the others. Pernambuco long constituted, and still does, we suspect, one of the principal slave-markets in the country; and the callousness and cruelty with which this inhuman traffic has always been carried on, have powerfully contributed to debase the minds and corrupt the morals of the inhabitants. Although within a few degrees of the equator, the climate of Pernambuco is remarkably salubrious, and rendered almost temperate by the refreshing sea-breezes. The comarca of Recife contains only three small towns, besides the capital, and these are too unimportant to require any particular description.

Olinda is situated upon a rocky hill, which, although not very high, is nevertheless the highest in the neighbourhood. Its appearance from the sea is beautiful and prepossessing; but this presage of elegance and grandeur is not realized on a narrow inspection. It is now in a state of great decay, having been deserted for the lower town of Recife. The elevations on which it stands are embosomed in dark woods, which seem coeval with the land itself; and being rent and broken in various directions, they present the most abrupt and picturesque scenery. The population of Olinda may amount to about seven thousand. When it was burned by the Dutch in 1631, it is said to have contained 2500 houses, and about 25,000 inhabitants. It was founded by Duarte Coelho Pereira about the year 1535, but it has continued to decline as Recife has advanced in prosperity. In the comarca of Olinda there are, besides the capital, four other towns, amongst which Goiana and Iguarassu are reckoned considerable places. The latter, distant from Recife seven leagues to the northward, and two from the sea, is one of the most ancient towns of the province. It contains but a scanty population. Goiana, distant about fifteen leagues from Recife, and four from the sea, is a much larger and more flourishing place than the other. It is situated on the banks of a river of the same name, which here bends so considerably as almost to surround the town. Besides sugar, a great quantity of cotton is exported, and there is a large cattle-fair held every Thursday. The planters have the advantage of water-carriage to Recife, as the river for many leagues both to the north and south is one of the largest, and is influenced by the tide even above Goiana. This town, with the surrounding district, is supposed to contain upwards of 20,000 inhabitants. There are several other towns or villages which carry on a considerable trade, and being chiefly situated upon the river Capibaribe, they enjoy ample facilities for communication with the capital.

One of the most important places in Pernambuco is the Island of Itamarca, one of the oldest settlements in Brazil, and formerly a distinct captaincy. It is situated eight leagues to the northward of Recife, at a short distance from the mainland. The Dutch took it in 1633, built a fort on it, and of such importance did it appear to them, that for some time they contemplated removing the seat of government to the island; a plan which was overruled, although Itamarca appears to possess decided advantages as compared with the capital. In the year 1645 Joam Fernandes Vieira, the principal hero of the Pernambucan war, attacked the island, but did not succeed in obtaining possession of it. Subsequent attempts were made, with only partial success, and the Dutch did not surrender the fort until their expulsion in 1654. Itamarca is three leagues in length by about two leagues in breadth; it contains a considerable quantity of excellent land, and, with the exception of the immediate vicinity of Recife, is the most populous part of the province of Pernambuco. As the island produces excellent cane, there are here several sugar-works; and vines were formerly cultivated with great success. The shores are planted with cocoa-trees, amongst which are thickly scattered the cottages of fishermen. One chief source of the wealth to Itamarca is the salt-works, formed upon the sands which are overflowed by the tide at high water. Conception is the oldest town on the island; but the long village of Pillar, situated on its eastern side, is the principal settlement. The ants, the pest of Pernambuco, and indeed of all Brazil, are so numerous here, that whole plantations of mandioc and maize are sometimes destroyed by them. At the northern entrance to the channel of Itamarca is the port of Catuama, the second in importance in the province. Next to it, in the opinion of the inhabitants, is that of Tamandare, ten leagues south-west of Cape St Augustin; but Mr Henderson thinks this port the best of the whole. It is in the form of a bay, with a depth of water sufficient for large vessels, capacious enough to receive a fleet, and securely defended by a strong fort. Cape St Augustin is the only promontory on this part of the coast, and the most eastern land of South America. It has two forts, each of which defends a small port, and stands in latitude 8. 26. south. The comarca or province of Alagos is of comparatively little consideration. The capital, however, which bears the same name, is a place of considerable commerce, and has a population of 14,000 souls. The other towns belonging to Alagos are Maceyo, Porto de Pedras, and Penedo. The latter, the port of the great river St Francisco, is situated about seven leagues from its mouth. It is a flourishing place, and, with the district, contains about 12,000 inhabitants. The river, which is here a mile in breadth, rises only three feet in spring tides; but the town is exposed to injury when the freshes come down.

The western part of the province, or the sertam, is much more extensive than the maritime district; but it is very thinly inhabited, owing to the natural sterility of the soil, and the want of rain, which only falls during thunder showers. It contains several towns, the largest of which, called Barra do Rio Grande, is situated at the confluence of the Rio Grande with the St Francisco. One hundred miles below this town is that of Pilao Arcado, the second place in importance in the sertam. The population of the district has been stated at 5000 souls. Maize, mandioc, and melons are cultivated on the margins of the river, but all the country beyond its immediate vicinity is wild and sterile. There are a great many salt lakes at various distances from the river, and on the margins of these, salt collects, and forms a considerable article of trade. The great, indeed the only business of importance carried on in the sertam is the rearing of cattle, great herds of which range over the immense plains situated on either side of the mountain-chain already mentioned. The Sertanejos, as the inhabitants are called, occupy fazendas or cattle farms of such vast extent, that few know their bounds, although they attempt to calculate them by the hundreds of cattle pastured upon them. Their leagues, as in all other thinly-inhabited tracts, are of deceptive length, sometimes four miles. Their dress consists of jacket, hat, and long pantaloons or leggins, all of brown untanned leather, a tanned goat-skin over the breast, and a pair of coarse cotton drawers or trousers. When on horseback and on a journey, which is often the case, the Sertanejo takes his hammock and portions of his wardrobe along with him, and also carries his farinha, dried meat, and other necessaries. The usual colour of a Sertanejo is dark brown; and the complexion even of those who are born white soon becomes as completely tanned as the dress which they wear. The dress of the women is homely enough, and they are kept in a state of considerable restriction, seldom appearing abroad, or, if they do so, they are never allowed to take any part in conversation. There are no wild cattle in these sertams; but kine are exceedingly plentiful. The religion of the Sertanejos is confined to the observance of certain forms and ceremonies, and to the frequent repetition of a few prayers; but they have great faith in charms, relics, and other things of the same kind. The traffic of the sertam is conducted by pedlars, who give them, in exchange for their live stock, hides, and cheese, various trinkets, articles of luxury, and English cottons, which are now superseding the coarse fabrics of the country. The population of the whole province amounted in the year 1830 to 602,000 souls.

The following is a statement of the quantities of the principal articles of merchandise exported from Pernambuco during the year ending January 1836: Cotton, 52,142 bags; sugar, 17,520 cases, 2846 half cases, 56,996 barrels, and 9180 bags; hides, 91,492; coffee, 300 bags; rum, fifty-eight puncheons; Brazil wood, 1200 quintals; and mandioc 1217 bags; the estimated value of the whole being nearly one million sterling. The number of vessels which entered during the same period was 247, and their total tonnage 47,696. Of these, 179 cleared with cargoes, the rest in ballast. The trade of Pernambuco with Great Britain is more extensive than that with any other country. The goods chiefly sent thither are cotton manufactures, hosiery, lace, and small wares, with earthenware, leather wrought and unwrought, hardwares and cutlery, iron and steel, beaver and felt hats, brass and copper manufactures, apparel, slops and haberdashery, beer, ale, butter and cheese, glass, arms, and ammunition. It appears by the parliamentary papers, from which this statement of the exports is taken, that the trade of Pernambuco is on the increase. (R. R. R.)

PERNICIOUS ISLANDS, a group of islands in the Southern Pacific Ocean, about fifteen miles in circumference, and which were so called by Raggemein, one of whose vessels was wrecked there in 1712. They are supposed to be the Palliser Islands of Captain Cook. Long. 140. 45. W. Lat. 16. S.

PERONNE, an arrondissement of the department of the Somme, in France. It is 465 square miles in extent, and is divided into eight cantons, which are subdivided into 184 communes, containing 98,500 inhabitants. The capital is the city of the same name, situated on the river Somme, in a position marshy and almost inaccessible to an attacking force. It contains a fine market-place, five churches, and 946 houses, with 3760 inhabitants, who manufacture linen goods and tan leather. Long. 2. 50. 35. E. Lat. 49. 55. 30. N.

PERONES, a sort of high shoes, which were worn not only by country people, but also by men of ordinary rank at Rome. In the early times of the commonwealth, they were worn even by senators; but at last they were disused by persons of note, and confined to ploughmen and labourers. They were very rudely formed, consisting of hides undressed, and reached only to the middle of the leg. Virgil mentions the *perones* as worn by a company of rustic soldiers on one foot only.

PERORATION, in *Rhetoric*, the concluding portion of an oration, in which all that the orator had insisted on throughout his discourse is urged afresh with greater vehemence and passion. The peroration consists of two parts; recapitulation, in which the substance of what was diffused throughout the speech is briefly collected, and summed up with new force and weight; and the appeal to the passions, which is so peculiar to the peroration, that the masters of the art call this portion *sedes affectuum*.

PERPENDICULAR, in *Geometry*, is a line falling directly upon another line, so as to make equal angles on each side.

PERPIGNAN, an arrondissement of the department of the Eastern Pyrenees, in France, extending over 557 square miles. It comprehends seven cantons, divided into eighty-five communes, and containing 57,800 inhabitants. The capital is the city of the same name, the see of a bishop, and the seat of the departmental courts of law and boards of government. It stands on the left bank of the river Tet, about ten miles from the Mediterranean Sea. As a frontier place towards Spain, it is strongly fortified, and defended by a citadel. The cathedral is a fine building, but the city generally is not clean or elegant. It contains 2000 houses and 13,200 inhabitants. It has some trade in leather, woollen cloth, wine, corn, and cattle, and considerable contraband intercourse with Spain. Long. 2. 48. 30. E. Lat. 42. 41. 59. N.

PERRAULT, CLAUDE, a celebrated architect, was born at Paris in the year 1613. His father, an advocate of the parliament, caused him to study medicine, anatomy, and the mathematics; and he even took the degree of doctor of physic in the faculty of Paris. But Colbert, the celebrated French minister, having advised him to undertake a translation of Vitruvius, the studies in which he found it necessary to engage in order to understand that writer inspired him with a decided taste for architecture, and gave a new direction to his pursuits. When the Academy of Sciences was established, in 1666, Perrault was admitted a member of this body, and was employed to furnish designs and building-plans for the Observatory. But this edifice, which, with all its merits, is in a heavy style, was far from giving any indication of the talents which Perrault afterwards displayed. His grand work is the palace of the Louvre, the façade of which was designed by him, and is certainly one of the noblest monuments of architecture in the world. The building had been commenced, and even part of the façade raised according to the designs of Lavau. But Colbert, dissatisfied with these, which he justly considered as deficient in grandeur, and unsuitable to the nature of the subject, appealed to the genius of other architects; and Perrault produced a design so superior to those of his competitors, that it immediately obtained a decided preference. Nevertheless, before commencing the work, the king wished to have the ideas of the best artists of Italy; and with this view, Bernini, who then enjoyed a great reputation, both as a sculptor and an architect, was sent for from Rome, and received in France with the greatest distinction. But the pre-eminent merit of Perrault was, notwithstanding, fully recognised; his plans were adopted by the court, although objections had been strenuously urged as to the practicability of their execution; and a model constructed by the artist himself at length removed every doubt on the subject, by proving that the difficulties raised were altogether imaginary, and that the solidity of the fabric might be rendered commensurate with the beauty of the design. Such were the preliminaries of the erection of this monument, which may justly be regarded as the masterpiece of French architecture, and the finest edifice that exists in Paris. Perrault furnished designs for other works, particularly the triumphal arch erected at the extremity of the Rue Saint-Antoine, the foundation-stone of which was laid on the 6th of August 1670; and, in all his works, he displayed that superiority of genius, which was first exhibited in his translation of Vitruvius, particularly in the plates with which it was enriched, and which have ever been considered as masterpieces of their kind. The first edition of this work appeared in 1673, and the second in 1684, in one volume folio; after which the translator published an abridgement in one volume 12mo. To the same author we are likewise indebted for another work, entitled *Ordonnances des Cinq Espèces de Colonnes selon la Méthode des Anciens*, in one volume folio, forming a kind of supplement to the translation of Vitruvius, and containing explanations of several points which had not been touched upon in the notes to that work. Of his other productions the principal are, 1. Essais de Physique, 1680–1688, in two vols. 4to, and four vols. 12mo; 2. Mémoires pour servir à l'Histoire

Naturelle des Animaux, Paris, 1671–1676, in folio; 3. Recueil d'un grand Nombre des Machines de son Invention, for raising and transporting the heaviest weights, Paris, 1700, in one vol. 4to. Claude Perrault assisted his brother Charles in preparing the memoirs relating to the establishment of the Academy of Sciences, and that of Painting and Sculpture, and took a warm interest in the success of that institution. He died at Paris, on the 9th of October 1688, in consequence, it is believed, of having wounded himself whilst dissecting, in the Jardin du Roi, a camel which had died of some contagious disease; and the faculty of medicine caused his portrait to be placed amongst those of their most distinguished members. (A.)

Perrault, *Charles*, the brother of Claude, was born at Paris on the 12th of January 1628, and at the age of eight was placed in the college of Beauvais, where he distinguished himself in scholastic disputation, and in making verses with extreme facility, "indice trompeur d'un talent qui ne mûrit presque jamais." On leaving school, he found that burlesque was in vogue; and a friend having suggested to him the idea of translating the sixth book of the Æneid in the manner of Scarron, he executed the travesty in a manner which attracted the commendation both of Voltaire and of Marmontel. But when his ideas were matured by reflection, he ceased to attach any value to such effusions; and, having completed his studies, he was admitted as advocate, in which capacity he pleaded two causes with success. Colbert, however, soon deprived the law of his services, and, in the year 1664, appointed him first commissary for the superintendence of royal buildings, an office the duties of which he discharged with equal zeal and ability, nobly justifying the confidence of the minister, and regarding himself as the representative of men of letters and of artists at the court. The Academy of Painting, Sculpture, and Architecture, and that of Sciences, were founded on memoirs drawn up by Charles Perrault, who had now become comptroller-general of buildings; and he was admitted into the French Academy in 1671, in the room of the bishop of Léon. But the impracticable character of Colbert having at length wearied out his patience, he retired from his public situation, and, devoting himself to literature, produced his poem entitled *Siècle de Louis XIV.*, which appeared in 1687, and involved him in a war with the learned, by reason of his exalting the modern in comparison with the ancient authors. He defended himself, however, in the *Parallèle des Anciens et Modernes*, which appeared at Paris in 1688, afterwards attracted the notice of Bayle, and excited very considerable attention. One of his principal antagonists was Boileau, who attacked him with great asperity, and, as usual, had all the scoffers on his side; but at length they were, in some measure, reconciled, although, on the part of Boileau, the *amende* was made in a tone which savoured more of contempt than of conciliation. His poem on Painting was, however, generally admired; but his Tales in verse, entitled *Grisélidès*, *Peau d'Ane*, and *Souhaits Ridicules*, are prolix and heavy. Perrault died at Paris on the 16th of May 1703. Besides the works already indicated, he wrote, 1. Recueil des divers Ouvrages en prose et en vers, Paris, 1675, in 4to; 2. Courses de Têtes et de Bagues, faites par le Roi et par les Princes et les Seigneurs de sa Cour, en 1662, Paris, 1669, in folio; 3. Cabinet des Beaux-Arts, *ibid.* 1690, in folio; 4. A Translation of the Fables of Faërne; 5. Memoirs of his Life, for the use of his children; 6. *L'Oublieux* and *Les Fontanges*, manuscript comedies, which, in 1822, passed into the rich and valuable collection of M. de Soleinne. D'Alembert included the éloge of Charles Perrault amongst those of the members of the French Academy (tom. ii. p. 165.) (A.)

PERRON, Jaques Davy du, a cardinal, distinguished by his abilities and learning, was born in the canton of Berne in the year 1556. He was educated by Julian Davy, his father, a learned Calvinist, who taught him Latin and the mathematics; after which, by his own exertions, he became acquainted with the Greek and Hebrew, philosophy, and the poets. Philip Desportes, abbot of Tyron, made him known to Henry III. king of France, who conceived a great esteem for him. Some time afterwards Duperron abjured Calvinism, and embraced the ecclesiastical function in the Catholic Church; and having given great proofs of his wit and learning, he was chosen to pronounce the funeral oration of Mary Queen of Scots. After the murder of Henry III. he retired to the house of Cardinal de Bourbon, and took great pains in bringing back the Protestants to the Church of Rome. Amongst others he gained over Spondanus, who was afterwards bishop of Pamiers. He also contributed to engage Henry IV. to change his religion; and that prince sent him to negociate his reconciliation with the holy see, in which he succeeded. Duperron was consecrated bishop of Evreux whilst he resided at Rome. On his return to France, he wrote, preached, and disputed against the reformed, particularly against Duplessis-Mornay, with whom he had a public conference in the presence of the king at Fontainebleau. In 1604, he was made cardinal by Pope Clement VIII. at the solicitation of Henry IV. who afterwards nominated him to the archbishopric of Sens. The king at length sent him to Rome with Cardinal Joyeuse, in order to terminate the disputes which had arisen between Paul V. and the Venetians. It is said that the sovereign pontiff had such a high opinion of the address of the Cardinal Duperron, that he used to say, "Let us pray to God to inspire the Cardinal Duperron, for he will persuade us to do whatever he pleases." After the death of Henry IV. he retired into the country, where he put the last hand to his work; and, having set up a printing-house, corrected every sheet himself. He died at Paris in 1618; and, after his death, his works were collected and published at Paris in three volumes folio.

PERRUKE, Peruke, or *Periwig*, was anciently a name for a long head of natural hair, particularly such as great care had been taken in adjusting and trimming. Ménage derives the word rather fancifully from the Roman word *pilus*, hair. The Latins called it *coma*, and hence part of Gaul took the denomination of *Gallia Comata*, from the long hair which the inhabitants wore as a sign of freedom. An ancient author says, that Absalom's perruke weighed two hundred shekels. The word is now used for a set of false hair, curled, buckled, and sewed together upon a frame or cawl, anciently called *capillamentum*, or false perruke. It is doubted whether or not the use of perrukes of this kind was known amongst the ancients. It is certain, however, that they used false hair. Martial and Juvenal ridicule the women of their time, for making themselves look young by means of borrowed hair; they scoff at the men who changed their colours according to the seasons, and the dotards, who hoped to deceive the destinies by their white hair. But these oddities do not seem to have had any thing in common with our perrukes, and were at best only composed of hair painted and glued together. Nothing can be more ridiculous than the description which Lampridius gives of the Emperor Commodus's perruke; it was powdered with scrapings of gold, and oiled, if we may use the expression, with glutinous perfumes, to make the powder adhere. The year 1629 is reckoned the epoch of long perrukes; at this time they began to appear in Paris, whence they spread by degrees throughout the rest of Europe.

PERRY, Captain John, a repectable engineer, who resided long in Russia, having been recommended to the Czar Peter whilst in England, as a person capable of serving him on a variety of occasions relating to his new design of establishing a fleet and improving inland navigation. His salary in this service was L.300 per annum, besides travelling expenses and subsistence money on whatever service he might be employed, together with a further reward to his satisfaction at the conclusion of any work he should finish. After some conversation with the czar himself, particularly respecting a communication between the rivers Volga and Don, he was employed on that work for three summers successively; but not being well supplied with men, partly on account of the ill success of the czar's arms against the Swedes at the battle of Narva, and partly by the discouragement of the governor of Astracan, he was ordered, at the end of 1707, to discontinue his operations, and next year was employed in refitting the ships at Veronise, and in making the river of that name navigable; but after repeated disappointments, and a variety of fruitless applications for his salary, he at last quitted the kingdom under the protection of Mr Whitworth, the English ambassador, in 1712. In 1721 he was employed in stopping with success the breach at Dagenham, in which several other undertakers had failed; and the same year he was occupied about the harbour at Dublin, to the objections against which he then published an Answer He was the author of a work on the State of Russia, 1716, 8vo, and an account of the stopping of Dagenham breach, 1721, 8vo; and he died on the 11th of February 1733. These scanty particulars are all that is known of Captain Perry, who seems to have been a man of considerable ability and enterprise.

Perry, the name of a very pleasant and wholesome liquor, extracted from pears in the same manner as cider is from apples.

PERSAIM, or **Bassein**, a town of the Birman empire, and province of Pegu, situated on the river Irrawaddy, which is here called Persaim, and is navigable for ships up to the town. Owing to the inundation of the river, the town is built on piles of wood eight feet from the ground, which admit the tide under them to wash the place, which is the receptacle of every thing that is filthy. The houses are built of wood and mats. During the wars between the Peguans and Birmans this town was burned down, and has never recovered its former splendour. The British obtained, in 1757, a grant of land for the establishment of a factory, but this grant was never ratified by the king. Long. 95. 0. E. Lat. 16. 50. N.

PERSAUMAH, a town of Hindustan, in the province of Bahar, and district of Tirhoot, ninety miles north-east by east of Patna. Long. 86. 32. E. Lat. 26. 1. N.

PERSECUTION means any pain or affliction which one person designedly inflicts upon another; and, in a more restricted sense, it includes the sufferings which the Christians underwent on account of their religion.

Historians usually reckon ten general persecutions; the first of which took place under the Emperor Nero, thirty-one years after our Lord's ascension, when that emperor having set fire to the city of Rome, threw the odium of this execrable act on the Christians, who were consequently wrapped up in the skins of wild beasts, and worried and devoured by dogs, whilst some were crucified, and others burned alive. The second took place under Domitian, in the year ninety-five. In this persecution St John the apostle was sent to the Isle of Patmos, being condemned to work in the mines. The third began in the third year of Trajan, in the year 100 of our era, and was carried on with great violence for several years. The fourth took place under Antoninus the philosopher, when the Christians were banished from their houses, forbidden to show their heads, reproached, beaten, hurried from place to place, plundered, imprisoned, and stoned. The fifth began in the year of our Lord 197, under the Emperor Severus. The sixth began with the reign of the Emperor Maximinus in 235. The seventh, which was the most dreadful persecution that had ever been known in the church, commenced in the year 250, in the reign of the Emperor Decius, when the Christians were in all places driven from their habitations, stripped of their estates, tormented with the rack, and subjected to every species of suffering. The eighth began in the year 257, in the fourth year of the reign of the Emperor Valerian. The ninth took place under the Emperor Aurelian, in the year 284; but this proved very inconsiderable. The tenth began in the nineteenth year of Dioclesian, and in the 303d year of our era. In this dreadful persecution, which lasted ten years, houses filled with Christians were set on fire, and numbers of them were tied together with ropes and thrown into the sea.

But these reiterated and cruel efforts to put down the Christian religion, or at least to check its advancement, proved utterly abortive; perhaps, humanly speaking, they served, in no inconsiderable degree, to accelerate its progress towards the complete triumph which it at length obtained in the reign of Constantine. It has often been remarked, that the blood of the martyrs is the seed of the church, and, in one sense, this is true. Of all the aggressions on freedom of thought and belief committed under the influence of bigotry, fanaticism, or, worst of all, a hard-hearted and unfeeling policy, persecution is the most bootless, short-sighted, and foolish. In every case, it is certain to defeat its own object. It may give even to error a temporary eclat of popularity which it could never otherwise obtain; whilst truth, not only unskathed, but purified, by the fire, issues from the furnace, like gold seven times refined, and presents herself to the eyes of mankind in renovated beauty and glory. Infidel philosophers have told us, that polytheism was naturally tolerant. But the history of the Christian church says No, and proves that Paganism, like every other system of established error, was prone to employ force against evidence, and to persecute where it despaired of convincing.

PERSEES, or **Parsees**, the descendants of a colony of ancient Persians, who took refuge in Bombay, Surat, and the vicinity of those cities, when their own country was conquered by the Mahommedan Arabs. They are a gentle, quiet, and industrious people, beloved by the Hindus, and living in great harmony amongst themselves. The Persees were for a long time but little known. The ancients seldom speak of them, and what they say seems to be dictated by prejudice. On this account, about the end of the seventeenth century, Dr Hyde, who thought the subject both curious and interesting, attempted a deeper investigation of a subject which till then had been but very little attended to. He applied to the works of Arabian and Persian authors, from which, and the relations of travellers, together with a variety of letters received from persons in India, he compiled his celebrated work on the religion of the Persees. Other accounts have been given by different persons, as accident threw information in their way; but the most distinguished is that by M. Anquetil-Duperron, who undertook a voyage to discover and translate the works attributed to Zoroaster.

PERSHORE, a market-town of Worcestershire, in the hundred of the same name, 103 miles from London, on the great road to Worcester. It stands on the river Avon, near its junction with the Bow, by which some internal navigation contributes to the extension of its trade. It is well built, and has a good market, which is on Tuesday, with two fine parish churches; and in the parish there are three chapelries. The population in 1801 amounted to 1573, in 1811 to 1815, in 1821 to 1963, and in 1831 to 2080.

PERSIA.

From the remotest period of antiquity Persia has been celebrated as one of the most powerful empires of the East, the seat of wealth and luxury when Europe was in a state of barbarism. The conquest of Babylon was the commencement of her future greatness; and her warlike monarchs continued their victorious course until they had established a kingdom which extended from the shores of the Mediterranean eastward to the Indus. Their progress westward was resisted by the bravery of the Greeks, by whose united force, under Alexander of Macedonia, Persia was finally subdued, and remained for several centuries under the sway of Greek sovereigns. Her independence was finally re-established under a race of native monarchs about 200 years before the Christian era; and though again subdued by the Moslemin armies, by the Tartar hordes of Genghis Khan and Tamerlane, and by the Afghans, Persia emerged into independence under a native dynasty in 1506, under whose rule the country has ever since remained.

The most fallacious ideas have generally been entertained in Europe respecting the remote countries of the East. These have been famed in all ages for wealth, for boundless magnificence, and for the richest products both of nature and art; and it is remarkable that Persia should have been the peculiar subject of these hyperbolical descriptions, a country of rugged mountains and arid deserts being the least likely to realize them. Nor has the illusion been fully dispelled by modern travellers, several of whom, though they no longer represent Persia as a fairy-land, have yet failed to convey a true impression of its decay and misery. The following account of its geography, its population, commerce, resources, manners, and institutions, is founded on the well-authenticated accounts of those who have recently visited that country, and who have had access to the best sources of information.

The boundaries of Persia have been variously stated, and they have fluctuated with the vicissitudes of war and revolution. The Euphrates and the Tigris, with the mountains of Armenia and Koordistan on the west, the Persian Gulf on the south, the arid and saline deserts on the east, which extend as far as the Indus, and rise into the mountain deserts of Hindu Coosh and Parapamisus, and the Caspian Sea and the mountains of Caucasus on the north, may be considered as the present boundaries of this empire. Geographers have sometimes assigned the Indus as its eastern limit; but the intervening countries of Caubul and Candahar cannot with any propriety be included in the dominions of Persia, having been long independent of her authority; and still less can the southern deserts of Mekran and Beloochistan, which would make the Indian Ocean the southern boundary; since we know, from the most recent accounts of travellers, that they are inhabited by fierce and independent tribes, who have long thrown off their allegiance to the Persian monarchs, and live in wandering communities under their own sheiks.[1]

With the exception of the provinces of Mazanderan and Gheelan, and other parts of less extent, the general aspect of Persia is that of poverty and barrenness. It has been termed a country of mountains; and a large portion of its surface is certainly mountainous, diversified with extensive tracts of desert plains, in which salt is the chief production, and, in a small proportion, chiefly along the banks of the rivers, with beautiful valleys and rich pasture-lands. The valleys are not generally broad, but some are of great length, being often more than a hundred miles. The greater part of the country may be described as a table-land, supported on every side by high mountains. This table-land stretches on a level along a great part of the Persian Gulf and the river Tigris on the south, and, under various appellations, along the Caspian Sea, forming a strip of country which extends about sixty miles to the foot of the Elburz Mountains, and there meets with the plains of Tartary on the north. The height of this plateau, though it was not accurately measured, is estimated by Frazer at 3000 feet; and from its elevated surface the mountainous ranges rise to various heights, sometimes enclosing valleys, or apparently insulating the plain, which often surpasses them in extent. A level country also extends from the mouth of the Indus, along the shore of the Indian Ocean, to the river Euphrates; which is an arid desert, that for a distance of more than twenty degrees does not boast of a single river which is navigable above a few miles from the ocean, and presents to the eye one continued and cheerless succession of sandy plains.[2]

The aspect of the Persian mountains is peculiarly bare and forbidding, rising abruptly from the plain, and presenting nothing to the eye but huge masses of gray rock piled upon each other; and even when they are covered with a little mouldering rock, they are still without either wood or shrubs. If for about two months in spring a scanty verdure clothe their sides, it is scorched by the heat of summer, and the country soon resumes its former barren aspect. Nor is the appearance of the plains more inviting, consisting for the most part of gravel washed down from the mountains, or of other equally unproductive matter, in deep and extensive beds, or of a hard clay, which, where water is wanting, as in most parts of Persia, is bare and barren. "The livery of the whole land," says Frazer, "is constantly brown or gray, except during the two months of April and May." Amongst other disadvantages, Persia labours under a general scarcity of water. The rivers are few and small, and rivulets by no means common, so that irrigation can only be applied to a small portion of the land. "In the best districts," says the above-mentioned traveller, "the small proportion of cultivated land resembles an oasis in the desert, serving by contrast to make all around it more dreary. Plains and mountains are equally destitute of wood: the only trees to be seen are in the gardens of villages, or on the banks of streams, where they are planted for the purpose of affording the little timber that is used in building: they chiefly consist of fruit-trees, the noble chinar or oriental plane, the tall poplar, and the cypress; and the effect which a garden of these trees produces, spotting with its dark green the gray and dusky plain, is rather melancholy than cheering. In picturing, therefore, to the imagination the aspect of a Persian landscape, or indeed the landscape in any of the contiguous countries to the north and east of it, the mind must endeavour to divest itself of every idea that gives interest or beauty to a European scene. There are no beautiful or majestic woods, no verdant plains or grassy mountains, no winding rivers or babbling streams, no parks or enclosures, no castles or gentlemen's seats, no sweet retired cottages, with their white walls glimmering through foliage."[3]

[2] History of Persia, by Sir J. Malcolm, vol. i. chap. i.; Morier's Journey, &c. p. 393; Frazer's Narrative of a Journey into Khorassan, p. 162.

[3] Frazer's Narrative, p. 163.

As already mentioned, the provinces of Mazanderan and Gheelan adjoining the Caspian Sea, with parts of Azerbijan and Armenia, form exceptions to this general description. These provinces are divided from each other by the great range of the Elburz Mountains, which are connected with the mountains of Armenia, and with the mighty Caucasus chain, and eastward, by a continuous chain, with the great ridge of the Hindu Coosh. They take an easterly course along the shore of the Caspian Sea, and send various ramifications southward; whilst other elevated ridges spring from the Caucasian Mountains, and penetrate the country in a south-east direction, dividing the provinces of Irak and Kusistan, and extending along the shores of the Persian Gulf, and with other parallel chains farther in the interior, into the province of Mekran. The Caucasian chain forms the barrier between the empires of Turkey and Persia; it occupies the space between the Black Sea and the Caspian; and it is inhabited by barbarous tribes, who owned at any time but an imperfect allegiance to Persia, and who have been now brought chiefly under the more rigorous sway of Russia. The Elburz Mountains present their loftiest face to the interior desert: yet they sweep down in a manner so gradual, that the valleys and ravines which they form are found to contain rich and fertile lands, well watered by numerous rivulets, and well cultivated and peopled. The loftiest peak of this range is Mount Demavend, which rises to the height of 10,000 feet. Here is that remarkable pass, forming a strong barrier against the progress of an invader, which was denominated by the ancients the Caspian Gates, and which for twenty-eight miles is a narrow road between high rocks, through which a single chariot could scarcely pass, and where a handful of men might oppose the advance of an army. These districts are beautifully diversified with wood, water, and mountains, in their most varied forms, and present a luxuriant verdure all the year round. On the northern side of these mountains, the provinces of Mazanderan and Gheelan, and the district of Astrabad, are equally fruitful and productive. Mazanderan is most celebrated for its culture of rice, which is of very superior quality. In the central provinces of Fars, Irak, and Khorassan, the valleys are generally level; in Azerbijan, to the west of the Caspian Sea, they lie between a succession of eminences; and Kurdistan, to the north, is almost one immense cluster of small mountains, intersected occasionally by loftier ranges, on which extend table-lands of great elevation, and subject to extreme cold, as in other parts of Persia.[1] The salt deserts which occur in various parts of the country form one of the most striking objects in its scenery, and may be distinguished from the general dreariness of the country by a saline efflorescence, which is seen glistening in the rays of a fierce sun. This appearance, extending over an immense plain, varied by a black rock here and there protruding from its surface, its image contorted into a thousand wild and varying shapes by the effect of the mirage, which produces the most curious optical illusions on those wide extended level tracts, is a sure indication of the total desolation which reigns around. The most remarkable of these salt deserts is that which extends northward from Helmund, the Elymander of the ancients, a river which takes its rise to the north of Cabul, in the range of hills that divide the country of Beloochistan from Lower Mekran, a distance of about 400 miles. In breadth, from Nooksy north-west to Jalk, it is nearly 200 miles. There are also extensive salt deserts in the provinces of Fars and Kerman, so that a large portion in the very heart of the country is desolate; and another great salt desert extends north-east from the western limit of Khorassan along the provinces of Kashan and Ispahan, and continuous with the deserts of Fars, Kerman, and Seistan; several mountainous projections, however, and cultivated tracts, intervening. This desert occupies a great space in the centre of the country: it extends north-east from the provinces of Ispahan and Fars as far as Tubbus, and with somewhat more frequent interruptions to Toorsheez; and on the east it is encroached on by projections from the more cultivated districts of Furrah, Subsawur, and Herat. The appearance of these deserts is not altogether uniform. In some places the surface is dry, and produces plants which thrive in a salt soil; in others the saline efflorescence is seen on a crackling crust of dry earth; marshes occupy a considerable portion of this country; and there is accumulated in the winter months water, which is evaporated during the heats of summer, leaving a quantity of salt in cakes upon a bed of mud. In some places the soil is a perfectly hard-baked and barren clay; and in others, again, sand abounds, which is formed into hillocks in the shape of waves by the wind, and is so light and impalpable that it is blown aloft in clouds, as in the Arabian deserts, by the violent north-west winds which prevail in summer, and proves dangerous, and frequently fatal, to travellers.[2]

Rivers.

Persia has hardly a single river that can be termed navigable, for the Euphrates and Tigris cannot be considered as running within its territory. The Karoon, which flows into the Euphrates through the province of Kusistan, and the Aras or Araxes in Azerbijan, which flows into the Black Sea, neither of them being considerable streams, are still its two largest rivers. The Helmund cannot with any propriety be termed a Persian river, as it flows eastward of Persia, through the independent territory of Afghanistan.

Soil an
produc

The nature of the soil in Persia may be inferred from the description given by travellers of the aspect of the country. Yet it is extraordinary how vegetation thrives in the country, even with the rudest cultivation, whenever there is the smallest supply of moisture. Morier mentions, that in the plain of Bushire, which stretches into the interior from the Persian Gulf, which all travellers agree in calling a barren land, and which has no other moisture than the dews, and occasionally winter showers, the seed produces one hundred to seven; and that a sprinkling of seed, with the most superficial furrows, returns everywhere in this district abundant produce. The same traveller observed, in his journey from Teheran to Tabriz, several spots where, by the aid of water, the country was one carpet of verdure. Water in Persia is so essential to vegetation, that almost the only species of improvement which is carried on is the construction of subterranean canals, for the purposes of conveying water to lands which are destitute of any natural supply. These canals, when they are finished, are often let at high rents. Frazer mentions one small stream which brought an annual rent of 4000 rupees, equal (the Persian rupee being valued at 1s. 4½d.) to L.375; and another canal, opened by the governor of Kauzeroon, and employed in irrigating a fruit-garden, was rented at five or six times that sum. The products of Persia are, wheat of the finest quality, barley, and other grains. Rice might easily be produced in the southern provinces, were it not for the deficiency of water, of which this grain requires so large a supply. The vine flourishes in several provinces; and the wine of Shiraz has often been highly celebrated, as well as the wines produced from grapes raised upon the side of the Caucasian Mountains. The vines at Shiraz are trained as standard bushes, without any support, and are set, with some attention to regularity, from eight to ten feet asunder. The mulberry is produced in great abundance in the northern provinces of Mazanderan and Gheelan, of which silk is one of the great staples, and also in other parts; and the rich and well-watered plains of Gheelan and Mazanderan yield in abundance the sugar-cane, though the art of refining is not understood in this rude and semi-barbarous country. Amongst the other products of Persia which, being useful, are articles of trade, are gum tragacanth, assafœtida, the plant of which grows in abundance on the plains and hills all around the city of Herat, yellow berries, saffron, henna, but not so fine as that of Egypt; madder roots, which grow wild upon the mountains, and are brought down for sale by the Eelauts and other wandering tribes. Indigo is cultivated near to Kherat and on the Laristan, but is not so fine as the indigo of India, which is largely imported into Persia. The leaf is used for dyeing the beard, a curious fashion in Persia, as in other parts of the East. Cotton is produced to supply the internal consumption; and also hemp and hops. Fruits are produced in the garden-grounds in great abundance and perfection. The date is one of the most important products, being used here, where the climate is extremely hot, as an article of food, in the same manner as in other parts of the East. Those produced at Dalakee, in the province of Fars, are celebrated over the country for richness and flavour. The other fruits are pomegrantes, a luscious fruit here, and much superior to those which are produced in Turkey, some that Morier saw being twelve inches in circumference; sweet and water melons, the shaddock, limes, oranges, for which the climate of the high table-lands is too cold, although they grow to perfection on the plains and on the banks of the Caspian Sea; apples, pears, apricots, pistachio-nuts, walnuts, and some others. Timber is scarce on the arid plains, but in more favourable situations the soil seems well adapted for the growth of wood, and indeed of trees of every description. The mountains of Gheelan, Mazanderan, and Azerbijan are clothed with the finest woods, amongst which are the oak, the beech, the elm, the alder, boxwood, with thickets of wild cherry and thorns, and luxuriant vines climbing up the trunks of the trees, and hanging in wild festoons from the one to the other. These form a striking contrast to the long ranges of naked and barren mountains in the central and southern provinces. In several provinces grows the poppy, from which is made opium of a very fine quality. The liquorice-plant covers the plains of Merdusht, and the neighbourhood of Shiraz. The tamarind, which flourished near the water-courses, and several of the thorny plants that sprinkled the same districts, had been superseded, when Frazer visited these parts, by various aromatic herbs, amongst which a species of fragrant rice was abundant. The most interesting of all the plants is that which yields the gum ammoniac. It resembles hemlock, and rises to the height of from three to six feet. It is remarkable in its season for its rich dark-green verdure; and it is then so full of juice, that on the least scratch it flows in streams to the ground, and congeals on the stalk. It is thus gathered for sale. Such vegetables as carrots, turnips, cabbages, spinach, beet-root, and the like, are common. In the more fertile parts of Persia flowers grow to great perfection and luxuriance; the rose, and every variety of the crocus species, primroses, violets, lilies, hyacinths, and others no less lovely than unknown.[1] Aromatic and thorny plants, and beautiful mountain shrubs, also abound, and clothe the ground in all the rich attire of luxuriant vegetation.

[1] Sir J. Malcolm's History of Persia, vol. i. p. 5.

[2] Frazer's Narrative, &c. chap. xi.

Notwithstanding the numerous ranges of mountains which intersect the country of Persia, its mineral products are of little value, partly from ignorance of the art of mining, and partly from the general indolence of the inhabitants, owing to the discouragement of tyrannical and rapacious rulers. Morier supposes that coal of a very fine quality must exist in the northern provinces of Mazanderan, by the account he received from the prime minister of a stone which is burned in that province instead of wood or furze, the common fuel in other parts of Persia, and very scarce. He did not learn, however, that any mines were worked. There are, nevertheless, copper mines in the mountains, from which the metal is extracted in such quantities as to render it an article of exportation; and there is little doubt that iron and silver would be obtained if proper means were applied. The mineral production most common in Persia is salt, which, as has been already mentioned, covers vast tracts, and occurs everywhere in great abundance. All the lakes are salt, and every considerable collection of water is impregnated with this mineral. Salt mines are also found in different parts. At Nishapore, in the north, there is a salt-mine consisting of three excavations, in each of which a vein of salt is found from six to eighteen inches in thickness. The salt is beautifully white, and the crystals so clear that Mr Frazer could see distinctly through a mass two inches in thickness, as through a pane of glass. This mine pays a small rent, and the salt is highly esteemed throughout the country. One of the most remarkable productions of Persia is naphtha or bitumen, which is burned by the natives in lamps instead of oil, and also answers all the purposes of pitch, being used in covering the bottoms of the vessels which navigate the Euphrates. It is found in pits three feet in diameter and from ten to twelve feet in depth, which are gradually filled from springs. There is also another species of white naphtha, different from the other, which is found floating like a crust on the surface of the water, and affords a more agreeable light than the black naphtha. A black and liquid petroleum of an agreeable odour flows in small quantity from a mountain in Kerman; it is reserved for the use of the king, and is given away in presents. The mines are carefully sealed and guarded. The northern mountains of Persia contain considerable varieties of valuable marble; and the turquoise stone, which is peculiar to the country, is found in the mountains of Khorassan. The mines which produce this stone were visited by Frazer, who gives a detailed account of their produce, as well as of the very rude manner in which they are worked. The hills in which these stones are found consist of a very red and brown rock. The whole range is deeply tinged with iron. The substances of which the rock is composed are a dead gray earth, heavy hard brown rock, soft yellow stone, and a rock which is pervaded with specular iron-ore. There are five principal mines or pits from which the gem is taken. The mode of management in these mines, which from time immemorial have furnished these highly valued gems, is the most wretched that can be conceived. There is no system whatever, neither skill nor ingenuity, in the mining process; nor any sort of contrivance to economize either labour, or time, or materials. They are not even at the pains to remove the refuse, which soon encumbers and finally puts a stop to their operations; and they break down, quite at random, with picks and hammers, the rock which forms the walls and roofs of the mine, without any attention to preserve the veins in which the gem appears. No shafts or chambers are formed on any regular plan; and if water collects in the mine, they have no means of drawing it off; and, finally, they have no plan for freeing the precious material from the rock in which it is embodied, with the least possible injury.

Climate.

The climate of Persia, in which, according to its latitude, heat should predominate, is considerably modified by the height of the ground; so that, according to Kinneir, the traveller may pass in a few hours from the air of Montpellier to the cold of Siberia.[2] It is intensely cold during the winter; indeed the highest ranges of mountains are covered with snow during a part of the year, and some of the highest peaks throughout the whole year. Demawend, in the Elburz Mountains, which rises to the height of about 10,000 feet, was seen by Morier buried in deep snow in May; and in 1810, Kinneir mentions that the mountains were covered with snow in July. Severe storms also prevail. To the north of Shiraz, especially, cold predominates, insomuch that in the vicinity of Teheran and Tabriz all communication is frequently cut off for several weeks between these cities and the adjoining villages. The cold commences in October, and the winter is ushered in with severe storms of snow. Frazer, after leaving Shiraz, suffered severely from cold in this month. The thermometer fell to twenty-eight degrees, and on the next morning, the 27th of October, to twenty degrees; and in the following month he arrived at Teheran, after encountering so severe a storm of snow that a traveller was carried to a caravanserai frozen to death on his horse. In January, when Frazer was at Nishapore, which is in the north of Persia, in about lat. 36. 25. the thermometer fell during the night to sixteen, nineteen, and twenty degrees, and rose during the day to forty in the shade; and in many parts the temperature varies between the night and the day from sixty-four to twenty-five and twenty-six. The cold, especially to the north of Shiraz, continues, with short intervals of warmer weather, till March or April. At Teheran, which is in the north of Persia, near the Elburz Mountains, Morier describes the progress of the season and the vicissitudes of the temperature. On the 10th of March there was a fall of snow, followed by an intense frost. On the 23d, the mildness of spring was experienced. On the 19th of April the thermometer rose to 82° in the shade. At Shiraz, Morier mentions, that after the middle of June the thermometer was scarcely ever under 100°. It then rose to 105°, 108°, and 110°. "When spring commences," says Sir J. Malcolm, "there is perhaps no spot in the world where nature assumes a more lovely garb than at Ispahan; the clearness of its streams, the shade of its lofty avenues, the fragrant luxuriance of gardens, and the verdant beauty of wide-spreading fields, combine with the finest climate to render it delightful."[1] The regularity of the seasons in this part of Persia is extraordinary, and affords a remarkable contrast to the sudden changes which take place in the northern provinces. In Bushire, to the south of Shiraz, Frazer states the range of the thermometer in July to be from 103° to 109°; but during the night it remained at 90°. About the end of August the weather became cooler, and the thermometer fell to 86° and 87°, and gradually during the day to 75° and 70°. In these southern regions, which include the provinces of Kerman, Laristan, Fars, and Kusistan, situated between the mountains and the shores of the Persian Gulf, the heat is increased by the barren and sandy plains with which this tract abounds. The hot winds known under the name of the simoom or sirocco prevail occasionally, but are not attended with danger, owing to the narrowness of the space between the sea and the mountains. In winter and spring the climate is delightful. It is never very cold; and snow seldom falls on the southern face of the mountains by which these provinces are divided from the north of Persia.[2] Upon the whole, however, the climate of this country, notwithstanding the sudden transitions from heat to cold in some of the provinces, is very healthy; the air is dry, and the atmosphere always clear, so that the brightest polished metal may be exposed to it without being rusted. Nor are the dews insalubrious; whilst at night the planets shine with a lustre unknown in the cloudy skies of the north. It seldom rains, and there are consequently none of those damp and pestiferous exhalations so common in the woody parts of Hindustan. The fertile provinces of Gheelan and Mazanderan, and the district of Astrabad, which are subjected to the periodical visitation of disease, form the only exceptions to this general character. The heavy rains which fall in these mountainous regions, stagnating in the deep forests, turn them into impassable marshes, which becoming putrid from the quantity of vegetable matter that they receive, exhale, during the heats of summer and autumn, a most pestilential vapour, so that the wandering tribes of these countries fly from its influence, and prefer living on the verge of the burning sand, and carrying their water from the distant river, to the least exposure to these noxious effluvia. Those who are forced to remain suffer severely from fevers, putrid as well as intermittent, from dropsies arising from cold, rheumatic affections, palsies, and other maladies. The appearance of the people, however, Frazer remarked, did not indicate either weakness or disease, being remarkably stout and athletic in their persons.

---

[1] Frazer, chap. xxiii.

[2] Geographical Memoir of the Persian Empire, p. 21.

The domestic animals of Persia are the camel, the horse, the mule, the ass, the goat, sheep, cow, &c. The Persians are expert and fearless horsemen; and they have different breeds of horses peculiar to the country. The native horse of Persia has been improved, both in strength and bottom, by an admixture of Arabian blood. But the original breed, which is now restored, is a tall, lank, ill-formed, and generally vicious animal, which often vents its rage upon its neighbours or its riders, by kicking or biting them. It is useful, indeed, for hard work; but is not to be compared, for the purposes of riding, with the action and docility of the Arab. There is another race of horses, reared by the Turcoman hordes, not so much distinguished by grace or beauty, as by its hardiness and patience of fatigue, for which it is celebrated all over Asia. It is said to have been crossed with an Arabian breed imported by Nadir Shah. The native horses are noted for size and bone, which appear to be indigenous; but figure and blood they owe to their Arab progenitors. "They have," says Frazer, "large and powerful quarters, resembling those of the English horse; the shoulders are often fine; their legs clean and strong; though generally spare of flesh, what they have is firm and good;" and not being burdened with a load of fat, they support the weight of the rider for an astonishing length of time. Their powers of endurance are almost incredible. They will carry their riders for seven or eight days together at the rate of eighty or a hundred miles a-day. There is also a breed of ponies, fully as remarkable, if not superior to the large horses in their powers of enduring fatigue. Such horses cost a sum of money equal in value to from L.150 to L.200 sterling, and those of the best quality from L.350 to L.400. These horses are used in plundering expeditions; and they are chiefly prized on this account for their hardy qualities. In the parched and sandy tracts of Persia exposed to great heats, camels are preferred, for carrying burdens, to other animals, and they constitute the chief wealth of the inhabitants; but in almost all the other parts of the kingdom mules are more generally used, for which they are well fitted, by their extraordinary strength and activity, and their power of enduring fatigue. Sheep are very abundant in Persia, and constitute the wealth of the wandering tribes; but the latter pay no attention to improve the breed. The dog, though esteemed an unclean animal by the Mahommedans, is yet found so useful that every prejudice has given way; and a very fierce breed is maintained by the wandering tribes, for guarding their flocks and tents, and aiding in their field-sports. The desolate parts of Persia abound in wild animals, amongst which may be numbered the lion, which is seen along the woody banks of the rivers; the tiger, which is more rare; the wolf, the jackall, the hyena, the fox, found in great numbers of a white colour, the porcupine, the mangaush, the wild sheep, the mountain goat, the wild ass, the wild boar, the antelope, and deer in great variety. Tigers are seldom seen, but it is certain that they are to be found, as it is mentioned that the skin of a royal tiger, which was killed in the neighbourhood of Tabriz, was exhibited, and was in possession of Mr Campbell. A tiger was also seen by the shepherds at the time that he was at Tabriz; and one of the Persian princes had gone out to hunt, with a large retinue, in the hope of meeting it. The wild ass is common in Persia, but is extremely shy, and not easily caught. Morier mentions, that one morning in the desert they gave chase to two wild asses; but they distanced the horses at such a rate that they stood still and looked behind at them, "snorting with their noses in the air, as if in contempt of our endeavours to catch them." The hunters sometimes succeed in killing them, but it requires great dexterity and knowledge of their haunts; and then it is only by relays of horses and dogs upon the track which they are known to pursue. The same traveller also observed large herds of antelopes, to which he gave chase, but could never come up except with one big with young; so great is the speed of this beautiful animal. The wild hog abounds in Persia, and is exceedingly fierce. Frazer, along with a party of well-mounted Turcomans, joined in chasing a herd of them; and one being singled out, was assailed with swords and spears, which made no impression on his tough hide; and though wounded by a pistol shot, he continued his flight, until an old man, mounted on a powerful Turcoman horse, rode up and wheeled rapidly round, when the steed, trained to the work, struck the hog on the head with its heels, and tumbled it over dead on the spot. The wild sheep is a very fine animal, bold, portly, and very strong; thick like a lion about the neck and shoulders, and small in the loins; covered with short reddish hair curled loosely about the neck and fore-quarters, and bearing an immense pair of crooked and twisted horns.

---

[1] History of Persia, vol. ii. chap. xxiv.

[2] Ibid.

If the face of the country in Persia disappoint the European traveller, his expectations will be still less gratified by the aspect of the towns, which present to him one mass of misery, filth, and ruins; for which, forming his ideas of the eastern towns from what he has read of Ispahan, Bagdad, Shiraz, Bassora, and other cities famed in story, he can scarcely be prepared. He looks in vain for the hum of a crowded population and the bustle of business which animate the cities of Europe. Instead of the road crowded with passengers, vehicles, and an active traffic, bordered with hedgerows and green enclosures, and with gay habitations, he has to thread his way through the narrow and dirty lanes, amidst the ruins of mud walls and old buildings, amongst heights and hollows, and clay pits that produce bricks, and high inclosures that conceal the only verdure the place can boast; till at last he reaches the dilapidated walls of the city, and, entering the gateway, watched by a few squalid guards, he finds himself in a mean bazaar, or more probably in a confusion of mere rubbish. There are no streets, and scarcely a house; for it is only the dwellings of the poor which are seen, the houses of the rich being carefully shrouded from the view by high walls of mud or of raw bricks, very unseemly in their appearance; and outside of these are clustered, with the utmost contempt of order, the houses of the poor. There is scarcely room for a loaded ass to pass between the narrow passages that give access to these dwellings; and as no attempt is made to level the paths, the passenger has to make his way over all impediments, diving into hollows, scrambling amongst ruins, stumbling over grave-stones, or falling into holes, especially at night, as no town is lighted in any of these countries. The bazaars are the only thoroughfares which deserve the name of streets; and these have received merited praise from many travellers, namely, those of Shiraz, the continuous bazaars of Ispahan, which extend for miles, some of those at Teheran, Tabriz, &c., all of which are comparatively spacious, lofty, and built of materials more or less solid; though the majority of Persian bazaars are as wretched as the towns. These bazaars are generally arched over with well-constructed brick-work or clay, or, as in the inferior constructions, with branches of trees. Here, as in India, are collected all the different trades, the smiths, the braziers, the shoemakers, the saddlers, the cloth and chintz sellers, in their own quarter; but confectioners', cooks', apothecaries', bakers', and fruiterers' shops are dispersed in various quarters. Few houses in a Persian town exceed one story; and the general *coup d'œil* presents a succession of flat roofs and long walls of mud, diversified however by gardens, with which the towns and villages are often surrounded and intermingled, and in which are seen the poplar, the cypress, and the oriental plane. Almost all the towns of Persia have some defence, consisting generally of a high mud wall, which is flanked by turrets, and sometimes protected by a deep dry ditch or a rude glacis. Caravanserais are built in every town, for the accommodation of travellers, and are also found at every stage on the principal roads of the kingdom. These edifices are generally constructed of stone or brick, of a square form, and divided in the interior into separate apartments. They are surrounded with high walls and towers, as a defence against the attacks of robbers. The houses are generally built of mud, with terraced roofs; and their inner apartments are usually better than might be expected from their outward appearance. The villages are in general very rudely constructed. The common huts have often, instead of a terrace, a dome roof, in order to avoid the necessity of using wood, which is a very scarce article all over Persia, there being few trees on the arid plains.

Trades and manufactures.

Persia, though it has made no great or general progress in the mechanical arts, has nevertheless been distinguished for those finer manufactures which minister to the luxury of an eastern court. Raw silk is one of the most important staples of Persia, and it is produced more or less all over the country, but chiefly in the provinces of Gheelan and Mazanderan. In the former alone the annual produce amounts to about 900,000 lbs. Silk goods of a very fine quality are manufactured at Yezd; and those of Ispahan, Cashan, and Tabriz are held in great estimation. Silk stuffs are also manufactured in Resht, Lahajan, Fomen, Enzellee, cities of Gheelan, and marts of commerce; and velvets of very great beauty are made at Mushed, and in various other places, namely, Ispahan, Cashan, and Tabriz. Satins also are manufactured, but, as Frazer thinks, not of so fine a quality, and those which are imported from China are preferred. The silk is manufactured into handkerchiefs and other pieces of different lengths and breadths, called alcejahs, dereis, cussabs, peerahums, and taffetas. The city of Shiraz is celebrated for its gold embroideries, though these are now surpassed in other places. Its damasked steel knives and daggers are still esteemed; and it manufactures a good deal of coarse glass ware. All its manufactures have, however, declined since it ceased to be the capital of the country. It has likewise manufactures of arms, cutlery, coarse glass ware, tobacco-pipes, cotton cloths, cotton and woollen stockings, and wine. The cotton goods chiefly manufactured are chintzes or printed cottons, culumcars, peerahur shakees, resembling English long cloths, which have entirely superseded them; kudduks, narrow cloths of a fabric resembling nankeen, and of all colours, manufactured of a fine quality at Ispahan; kherboz, a coarse white cloth of a loose fabric, varying in quality, used chiefly by the poorer classes; and Ispahan stripes, another coarse cloth striped blue, purple, or gray, with other intermediate varieties. The chintzes and prints which are manufactured in many places are coarse both in texture and pattern, and are only used for inferior purposes. They are nearly superseded by the printed cottons of India and Europe, particularly the latter; and it was even said that the home manufacturer had petitioned for protecting duties. But it is not likely that any such measure will be resorted to; and even in this case it would, under the relaxed police of Persia, be easily eluded. Culumcons are distinguished by a pattern of wreathed flowers in gay colours, sparsely strewn upon a white, blue, red, or fawn-colour ground; they are used for inner waistcoats, linings of robes, &c., and are often of very high price. Wool is produced in great abundance all over Persia and the neighbouring countries in which pastoral habits prevail. The best wool is that of the province of Kerman, the mountains of which, hot and arid in summer, and intensely cold in winter, sustain large flocks of sheep and goats, which yield the finest wool. The wool of the sheep is of an excellent quality; and the goats produce a down which grows in winter at the roots of the hair, in the same manner as that of the Thibet or shawl goats, and nearly of as good a quality. This is spun into various fabrics, which almost vie with the celebrated shawls of Cashmere in warmth and softness, as well as in fineness and beauty of manufacture. This fine wool is found not only in Kerman, but more or less over all Khorassan and the countries to the eastward, the mountains of which are favourable to the animals which produce it. The other woollen goods of Persia consist chiefly of carpets, numuds, felted goods, and a variety of fabrics of smaller importance used by the inhabitants as clothing. Many of the chief towns are celebrated for the manufacture of carpets. Those of Kerman, of Yezd, of Boorojird, of the Turcomans, of Khorassan, of Ispahan, and of Azerbijan, are all beautiful, though of different fabrics and patterns. Numuds or fine felt carpets are sometimes of great beauty; but they are dear, and apt to be moth-eaten. Other felted and woollen articles of a coarser quality are manufactured for internal consumption. Swords, fire-arms, and cutlery are manufactured in many of the principal towns. Black handkerchiefs, rather less than 1½ yard square, coarse, and tweelled like Barcelona handkerchiefs, are manufactured everywhere, and serve for the head-dresses of the women.

Trade.

Persia carries on a trade with Turkey, Bagdad, Arabia, and the countries situated on the Persian Gulf. Of the raw silk of Gheelan, amounting, as already stated, to 900,000 lbs., about one fifth part is exported to Constantinople, Aleppo, and the other cities of Asia Minor; about one fifth is manufactured in the cities of Ispahan, Yezd, Cashan, and other towns of Persia celebrated for their silk manufactures; and the remainder is partly purchased by the Russians and carried to Astracan, and partly sent to Bagdad and its vicinity. Persia exports to India specie, dried fruits, dates, tobacco, wine, drugs, assafœtida, sulphur, raw silk, carpets, Kerman shawls, swords, combs, copper, saffron, &c. Horses form a considerable article of export to India. They are sent by sea from Bushire, where they are collected from the breeding districts in the southern provinces of Persia, and from Khorassan and the north-eastern districts by land through Afghanistan and the Punjab; and they serve for mounting the Indian cavalry, and supplying the great private demand for riding horses by the British in India. The imports from India are cotton goods, chintzes, and muslins, from Masulipatam, Moultan, Lucknow, Futtighur, Delhi, and other places; though these have now been in a great measure superseded by the English, French, and German stuffs, introduced from the ports of the Levant, from India, and by way of Russia. Persia receives from India indigo, which comes chiefly by sea, by the way of Bushire, on the Persian Gulf, or by land through the country of Afghanistan, or Balkh, to Bukharia, and thence by Herat to Persia. Spices are also amongst the Indian imports, as well as sugar and sugar-candy, the import of which forms one of the most important branches of trade between the two countries. The province of Mazanderan yields a coarse sugar; and there are many parts of Persia fitted for the growth of this article, yet the country depends chiefly on India for its supply. Gold and silver stuffs from Benares, precious stones, Cashmere shawls, iron, lead, and copper, make up the remaining list of imports. Persia exports to Turkey grain, raw silk, tobacco, paper, cotton, lamb and foxes' skins, carpets, silk and cotton manufactures, Kerman shawls, and salt; and receives in return specie, and European manufactures, brought from the ports on the Levant. From Europe, woollen, cotton, and silk goods are imported, imitation shawls, gold-lace, metal buttons, cutlery, watches, spectacles, spying-glasses, leather, earthen-ware, iron, copper, tin, quicksilver, and other articles. Iron is made in several parts of Persia; but the foreign iron is preferred, and it is imported from Russia, though it is but little used in these countries. Copper in sheets is much used, and is partly imported from Europe through Russia, and partly from India. There is a considerable demand for European silk goods, which are chiefly supplied by the French. Brocades and embroidery are also supplied from France, and Frazer mentions that of these he saw some magnificent samples at Teflis. In chintzes and printed cottons the French and German manufacturers have been more successful than the English in suiting the Persian taste; and every bazaar had, according to the well-informed traveller so often mentioned, a full display of their rich and glaring chintzes, whilst the more sober English goods lay neglected and unseen on the inner shelves. The European trade with Persia, as it is conducted at present, lies under the great disadvantage of an expensive land-carriage. There are various channels through which goods may reach the Persian market. First, they may be sent through Russia, and thence be transported down the river Volga to Astracan, and across the Caspian to the Persian towns of Resht or Astrabad. Accordingly, the countries around Astracan are supplied with the produce and manufactures of Europe by means of this great stream, which affords such facilities for the transport of heavy articles; and it is because Russia cannot herself furnish the necessary supply of goods which are imported from Europe, that the trade is not more considerable. The Russian trade across the Caspian Sea is carried on by twelve vessels, not exceeding a hundred tons, which bring to Astracan the sturgeon cured on the coasts of Gheelan and Mazanderan, besides returns of other Persian produce, and convey Russian or European goods to Resht, Lahajan, Balfroosh, and Astrabad. Secondly, goods may be sent by the Mediterranean to the ports of Trebizond and Redoubt Kaleh, situated at the western extremity of the Black Sea, or to Constantinople; and a considerable quantity of European goods reach Persia by this channel; but in the course of a long route of 1200 miles to Erivan, 200 more to Tabriz, and other 360 to Teheran, in all 1760 miles, they are subjected to an expensive land-carriage, to heavy and arbitrary imposts in their transit through the territories of rapacious chiefs, and to occasional attacks from the predatory banditti of those wild regions, and are consequently brought to Teheran at an expense of sixty-five per cent. The distance from Trebizond to Erivan is only about 140 miles, the road lying across very rugged mountains, though not worse than the roads over which much of the Persian traffic is carried on. The route from Redoubt Kaleh to Teflis, the capital of Georgia, is but 230 miles, and is through a safe country, free from imposts. Teflis, under the protecting government of Russia, has already, like Odessa, risen to be a mart of trade; and caravans regularly travel to Tabriz in eighteen or twenty days. European goods are now sent to this place in considerable quantities, namely, woollen cloths, cotton, printed and plain goods, some hardware articles, some refined sugar from Great Britain, silk and cotton manufactures from Lyons, and embroideries, cloths, &c. from other parts of France. There is another more direct channel through which a supply of European goods may be sent into Persia, namely, by way of Bushire; and, in point of fact, British manufactures to a considerable amount, especially cottons, are imported into this place, and thence conveyed to all the southern cities of Persia, namely, Shiraz, Yezd, Kerman, and Ispahan, whence they find their way still farther inland to Irak, Khorassan, and even to the farther regions of Tartary. These goods are, however, previously sent from Europe to Bombay, and thence to Bushire, being thus burdened with the useless expenses of this double voyage, which would be saved if they were sent directly to the Persian markets. After being loaded at Bushire, the goods must be carried over lofty mountains, by dangerous and wretched roads, before they can reach the market; and they are liable to heavy transit duties at all the towns through which they pass. Goods which are brought to India, and carried into the interior up its navigable rivers, are brought by the overland route through Caubul, Candahar, and Herat, or by Balkh or Bukharia. Certain it is that British goods carried on the backs of mules over dreary mountains find their way to these distant markets; the disadvantage of an expensive land-carriage, and other hazards, being counterbalanced by the great progress which Europe has made in manufacturing industry, and by the extended use of all sorts of ingenious machinery for saving labour, by means of which goods are manufactured and sold cheaper in the most distant markets than they can be furnished by the native workman.

The government of Persia is a pure despotism, which is subject to no control from the influence of laws or manners, and under which every man's life and liberty are at the mercy of the sovereign. He may exalt the lowest subject to the highest rank, or he may degrade, fine, imprison, maim, or put him to death, according to his will or caprice. Nor is this power allowed to remain dormant. The great Shah Abbas put to death an innocent traveller whilst asleep, because his horse startled at him; Aga Mahommed Khan put out the eyes of those who happened to look on his hideous countenance; and the modern history of Persia abounds with examples of horrid tyranny, of nobles and great men about the court being degraded from their rank, cruelly tortured and put to death, and their whole families, slaves and all, involved in their ruin. "The greatest noble in Persia," says Frazer, "is never for a moment secure either in his person or property; if a fit of rage, jealousy, or avarice, of which he is the object, happens to seize his sovereign, a word, a look from the despot subjects him to the most cruel insults; he may be beat, maimed, disgraced like the lowest groom; his person violated in a way degrading to humanity; his wives and daughters delivered to the lust of muleteers (the lowest class in Persia); and the little family honour a Persian can possess may be scattered to the winds, without the unhappy sufferer having the least hope of remedy, without even the event creating the least sensation; it is the shah's pleasure; and if he be firm in his seat, the lives and properties of his subjects are less than the dust beneath his feet." The evils of despotism in Persia are generally aggravated rather than abated by the personal character of the sovereign, which is for the most part cruel and despotic; his early training fostering in him every evil propensity. He is taught from his infancy to consider his subjects as created for his pleasure; he is initiated in the grossest sensuality; and, as if to train him to habits of cruelty, his preceptors are in the practice of taking him to witness executions, which in Persia are conducted with extreme cruelty, as if to steel his mind against humane feelings, and to habituate him to scenes at which other men would shudder. In general the kings of Persia profit by these early lessons; few of them are considerate or merciful; whilst with many, according to Sir J. Malcolm, "the habit of shedding blood becomes a passion, by a brutal indulgence in which, human beings appear to lose that rank and character which belong to their species."[1] It is remarked by Frazer, that all the servants of the king take their tone from him; and that when he is "cruel or merciful, peaceful or warlike, liberal or grasping, his disposition is reflected and multiplied throughout the whole land, down to the lowest ranks of society." Accordingly, throughout the different provinces of the Persian empire, chiefs and governors are everywhere seen improving upon the example of the sovereign; beating, maiming, and rending their property from the unfortunate cultivators who are placed at their mercy. There is no such thing as any protection for life and property in any part of this country; and the officers of government everywhere rob the people, and farther insult and maltreat them if they dare to complain. When the English embassy were travelling through Persia, they were compelled to witness numerous examples of tyranny and cruelty revolting to their feelings. The poor people were compelled to entertain the embassy; and, accordingly, the horses were turned without scruple into the barley fields of the impoverished peasantry. At one place, where one man complained that the produce of the field they were consuming was his sole subsistence, he was taken and severely beaten, and compelled, as Morier observes, to hold their horses as they were eating up his own property before his face. At another village, where the embassy was ordered not to stop, as it had been previously laid under contribution, and could not afford to entertain the embassy for a single day, the officer in charge (the mehmandar) insisted on a contribution in cash; and when they could not raise the money, he forcibly carried away the little furniture that was left in the houses, amidst the lamentations of the women, who were beating their heads, and lifting up their hands to the skies, but who were beaten with sticks and dispersed, by wretches who heeded not their cries.[2] Frazer relates the most shameful instances of the present king's extortion and cruelty. Whilst he was at Teheran, the traveller mentions that one of the courtiers fell under the displeasure of the Shah, who, knowing him to be rich, ordered him to be dragged before him, on a charge of embezzling the public money. During his examination he used some expressions which offended the king, upon which he ordered his officers to bind and to beat him; and in the mean time he began to revile him, and in his rage ordered him to be strangled. When the cord was round his neck, and he was on the ground, the king asked if he would give 100,000 tomauns for his life, to which he replied that he would give all he had; but the answer was considered as equivocal, the cord was tightened, and the blows rained thick upon him, until he acceded to the demand, and, being released, was allowed to return home. His prime minister, also, Hadjee Ibrahim, to whom he owed his elevation to the throne, was on some pretence, for the sake of his wealth it was supposed, degraded, and condemned to lose his eyes. Some expressions escaping him about ingratitude, the tyrant immediately ordered his tongue to be cut out; and under these tortures and persecutions this old and faithful servant of an ungrateful master at length expired. A monarch of Persia acknowledges no obligations but the ritual observances of his religion; and a blind superstition is thus substituted for the moral qualities of mercy, generosity, and justice. Every look being watched by parasites and flatterers, he becomes as impatient of the least opposition as he is insensible to the most devoted service. Distrust and terror reign amongst his courtiers, amongst whom falsehood, dissimulation, and specious show, supply the place of truth and loyalty. They have no means of preserving the royal favour but by flattery and fawning; and hence their whole object is to deceive and pillage, and, if they can with safety and advantage to themselves, to betray their tyrant. The effects of this system may be traced through all ranks about the court, even to the lowest menial. They are, with few exceptions, arrogant, overbearing, unprincipled, treacherous, and abandoned, in the greatest degree. "They stand continually," says Frazer, "on the brink of a dangerous precipice, and would be to be pitied, were it not that the bare-faced and hardened character of their vice" excites a feeling of contempt and detestation. Such is the character given of those who are attached to the various courts, and live in service with great men, including the military and other functionaries. The other two classes into which the population of Persia is divided are, those who live in towns, namely, merchants, shopkeepers, mechanics, and others; those who are engaged in agriculture; and, lastly, the wandering tribes of Eels. The inhabitants of towns are less exposed than others to the tyranny of their superiors, and they are more industrious; and, though far from strict in their morals, they are not so actively vicious. They are, however, cunning, deceitful, false, eager after gain, and cautious and penurious. Being constantly exposed to the most cruel extortion, and to torture, in order to force a disclosure of their wealth, they are forced to resort to the most disingenuous practices in self-defence. The Eels are a wandering race, rude and wild, and subjected only to patriarchal authority. They are, accordingly, impatient of restraint; and being at constant variance with all the neighbouring tribes, they are always engaged in depredations, and consider plunder and robbery as no crimes.

---

[1] History of Persia, vol. ii. chap. xxvi.

[2] Morier, Second Journey through Persia, p. 266, 267.

There is no class in Persia subjected to such tyranny and oppression as the farmers and cultivators of the soil. They are exposed to almost continual extortion and injustice; there is no definite limit to the amount of the demands made upon them. When the king demands money from his ministers, they have recourse to the heads of districts, who in their turn apply to the heads of villages, and these last wring it from the cultivators and farmers. Every tax, present, fine, or bribe, from whomsoever demanded in the first instance, ultimately falls upon them; so that the only measure of these demands is the ability to pay on the one hand, and the power to extort on the other. Yet there are exceptions to this uniform system of oppression; and when travellers have been admitted to view the Persian farmers in their houses and with their families, a degree of comfort and comparative plenty have been discovered, not quite compatible with the general tale of misery that was told. The explanation of this, however, is, that the peasantry and farmers sometimes contrive to baffle the vigilance of their oppressors, and to place beyond their reach a portion of their produce sufficient to insure to them a comfortable subsistence. They are described, however, as a race degraded by tyranny; as being devoid of truth, frankness, or honesty; treacherous, deceitful, deficient in gratitude and every other amiable disposition. The cruel acts of their rulers have familiarized them to deeds of blood; they set little value upon human life, and are apt to draw the knife in all their quarrels. They are easily inflamed into passion, and when under its influence they are careless of the result, the meanest inhabitant often venting imprecations against his superiors, and even against the king himself, which pass without any further notice than a few blows. They are active and intelligent, and these seem to be the only valuable qualities which they possess. They are also light-hearted, better humoured, and less grave and austere, than most of the other Asiatics; but their falsehood is proverbial; indeed habits of lying are so inveterate, that untruths flow as it were spontaneously from their tongue, even when no apparent motive exists. All travellers agree in this as one general characteristic of the Asiatics; the sure mark of the low state of civilization in that great continent. The politeness of the Persians, for which they have been so much famed, seems to consist more in the observance of a troublesome routine of ceremonies, and the use of complimentary language in all the forms of eastern hyperbole, than in any real courtesy. A Persian will say to a stranger that he is his slave, that his house and all that it contains, his horses, equipage, &c. all are at his service; but no one understands this in any other sense than an unmeaning form, which encumbers the intercourse of society, without refining it. In their persons the Persians are described as being handsome, active, and robust; lively in their imaginations, and of quick apprehension, but without any moral quality to attract esteem. The effects of the cruel despotism under which Persia groans, in thus degrading the character of the people, and also in checking the progress of science and of every useful art, are truly melancholy. The insecurity of life and property is the dead-weight which oppresses the country. It represses the efforts of industry; it paralyses the powers of invention, and every ingenious improvement; for no man will sow where he is not sure of reaping, or will task his ingenuity to produce what he may be deprived of the next hour. Frazer mentions the case of an ingenious manufacturer of porcelain, whose fame quickly spread till it reached the court, whence a message was despatched for him, that he might make china for the Shah. He well knew that he would receive nothing for his labour, and that he would, moreover, be forced to make china for all the nobles belonging to the court. He accordingly went to court, and mustering all the money he was worth, offered it as a bribe to the minister if he would report to the king that he was not the person that made the china, and that he had run away, nobody knew whither. The ruse succeeded. The minister sent his discharge to the man, who vowed that he would never make a bit of china, or attempt any other improvement, as long as he lived. It is a common practice to kidnap the best workmen in all trades for the use of the court and great men of the provinces, who never pay the workmen they employ. Hence every one avoids the reputation of excellence, except in the commonest trades; and thus, under the benumbing influence of this frightful despotism, improvement is nipt in the bud, and every useful invention is discouraged. There is no outlay of labour or of capital in expectation of any profitable return. No speculation is hazarded which promises any future advantage. No provision is made of any article, not even food, beyond the immediate demand. The people are reckless and indifferent to all but the passing hour, living from day to day uncertain whether they may have life or property on the morrow. No trees are planted; no extensive improvement takes place on the face of the ground; no public buildings of any solid materials are erected; no one thinks of posterity, but only how he can accommodate himself. All classes, however, are eager to accumulate money, as the means of support, or of purchasing safety in any emergency; and this desire is matured at last into an insatiable avarice, which is nowise scrupulous about the means of its gratification.

The king of Persia has a great variety of personal duties to perform. He gives audience at an early hour of the morning to his principal ministers and secretaries, who make reports of all state transactions, and receive his commands. He holds a public levee, which is attended by the princes, ministers, and officers of his court, at which rewards are distributed and punishments awarded. He then gives one or two hours to his personal favourites, or to his ministers. After the morning is past he retires to his inner apartments, where he is shrouded from observation. In the evening he holds a levee, and transacts business with his ministers and principal officers of state. This, however, is rather a sketch of what his employments ought to be, than of what they are. They may be interrupted by indolence or the love of pleasure; and the labour of business may be devolved, if such be his will, upon his favourites.

The business of the prime minister depends greatly on the personal favour of the king, which if he enjoys, he exercises great influence over all the branches of the government. Besides the chief ministers, the secretaries of state preside over the different offices or chambers of accounts; and regular accounts are kept of the receipts and disbursements of the whole kingdom.

The law of Persia, as in all other Mahommedan countries, is founded upon religion as contained in the Koran, and also upon tradition. Its rules are accordingly extremely vague and imperfect, and are administered by the priesthood, who often pronounce the most corrupt decisions, although the law, deriving its sanctions from religion, forms the only defence, feeble as it is, which the people possess against the violence and rapacity of power. Many cases are also decided by the law of custom or tradition, which, having reference to local as well as to common usages, varies in different parts of the empire, and is if possible a still more vague and imperfect code than the written law of the Koran. The ecclesiastical order in Persia, as in all other countries, eagerly grasping after power, insist that the law which they administer, being divine, should take cognizance of all cases. But the ordinary courts of common law, supported by the state, have succeeded in limiting their jurisdiction to cases of religious ceremonies, cases of inheritance, marriage, divorce, contracts, sales, and all civil matters; reserving to the ordinary courts the decision of criminal cases, such as murder, theft, fraud, breaches of the peace, and other offences. The order of priests have great influence in Persia. Before the reign of Nadir Shah, the whole power centred in the chief pontiff, who was deemed the vicar of Imaum, and engrossed vast wealth and influence. At the death of this high priest, no successor was appointed by Nadir Shah, who, besides, seized the treasures of the priesthood, in order to pay his troops. His grandson and successor appointed two persons to this high dignity, with a view of diminishing, by dividing, their power and influence. These priests are called Mooshtaheds; and there are now seldom more than three or four of this high dignity in Persia. They fill no office, receive no appointment, and have no specific duties, but are called by the voice of the public, from their superior learning, piety, and virtue, to be their guides in religion, and their protectors against oppression; and Sir John Malcolm observes, that they receive from the people a degree of respect and reverence to which the proudest kings would in vain lay claim. Their conduct generally agrees with the sacred character to which they owe all their importance; as they know, that in deviating from the strictest purity, they would lose all their influence, and could no longer expect to see the monarch courting popularity by walking to their humble dwellings, and placing them in the seat of honour when they pay a visit to his court. This order of priests exercise an important influence on the administration of the written law. Cases are constantly submitted to their superior knowledge; and there is no appeal from their sentence, except to a priest acknowledged to be superior in sanctity and in learning. The sacred character of these priests gives an authority to the decrees of the tribunals over which they preside, which the monarch is forced to respect. They are often effectual intercessors for mercy to the guilty; their habitations are considered as the sanctuaries of the oppressed; and "the hand of despotic power," says Sir John Malcolm, "is sometimes taken off a city, because the monarch will not offend a mooshtahed, who has chosen it for his residence, but who refuses to dwell amidst violence and injustice." Next in rank to these high priests, there is the Shaik-ul-Islam, literally the "elder or chief of the faith," who acts as a supreme judge in the court of written law. One of this class resides in all the principal cities; and under him is the cauzee, who has a council of moolahs or learned men as his assessors. In the lesser towns there is only a cauzee, from whom there lies an appeal, in cases of intricacy, to the cauzee of the larger towns, and finally to the supreme judge of the provincial capital. But, as in all countries, such as Persia, where there is no enlightened morality, and no control of public opinion, justice is venal and corrupt; the administration of the written law by the priests is extremely imperfect, and inadequate to its ends, insomuch that the suitor is deprived of every hope of justice; and it is only the administration of the customary law that offers any security, however imperfect, for justice between man and man. Even here, however, the administration of justice varies with the character of the reigning despot; and the judges in all their various gradations, from the king's lieutenants, the rulers of provinces, governors of cities, lay managers of towns, managers and collectors of districts, and heads of villages, aided by the officers under their authority, are active and just, or corrupt and cruel, as the monarch happens to be vigilant or virtuous, avaricious or tyrannical. Moral principle and the power of public opinion afford the only security for the pure administration of justice; and among public men trained in this school, the corruption of a judge is never so much as heard of. But such wholesome restraints do not exist in Persia. The European ideas of honour are scarcely known amongst any class. They are all venal and corrupt; and the iniquities which they themselves practise they but feebly condemn in others. Justice is often interrupted by the clashing authorities of the different courts; an evil which neither the sovereign nor his ministers are anxious to remedy, seeing that it adds both to their power and profit. A suit is very soon brought to a termination, and not at great cost; but considerable sums are often paid for a favourable decision. The most barbarous rules are still followed in the administration of the criminal law. In cases of murder the heir at law demands vengeance for blood; and when the guilt of the criminal is established, he is delivered into the hands of the injured person or his relations, to deal with him as they think fit. The revolting spectacle of private vengeance was witnessed by the English resident at Abushehr, as inflicted on the murderers by the relations of the deceased, who led their victims bound to the burial-ground, and there put them to death; the infant children of the person murdered being made to stab the murderers with knives, and thus to avenge their father's blood. The assassins of Aga Mahommed Khan, when they were executed, were stabbed by such of the younger children as could hold a dagger; and the successor of Nadir Shah sent one of his murderers to the females of his harem, who were delighted to welcome his executioners. The punishment of crimes in Persia is fixed by the written law, or, when the king interferes, by his arbitrary will. Fines, flogging, and the bastinado, are the common punishments of lesser offences. The disclosure of hidden treasures is enforced by tortures; and the inhuman punishment of putting out the eyes has long been practised in Persia, as in other countries of the East, on the relations of the reigning family who may aspire to the throne, or on the chiefs of tribes whom it is desirable to deprive of power, though not of life, and sometimes on the male inhabitants of a rebellious town. Criminals are put to death by strangling, decapitation, or stabbing; but in aggravated cases the most inventive cruelty is practised in devising modes of torture. In some cases, life is for a time preserved in protracted pain; in others persons are empaled, or their limbs torn asunder by the elastic bound of trees which have been bent for the purpose, or they are cast headlong from a high tower; and the history of Persia abounds with examples of tyrants glutting their vengeance on their victims by the most shameless insults and horrid injuries. In Persia women are seldom publicly executed, but they suffer dreadful violence in the recesses of domestic tyranny. When they are of high rank, the comprehensive injustice of the East often includes them in the punishment of their husbands or fathers; and they are given away as slaves to the lowest and most infamous classes of the community, such as mule-drivers. They are also sometimes tortured, in order to force from them a disclosure of wealth which they know to be concealed.

Revenue.

The collection of the revenue is intimately connected with the administration of justice, the same officer presiding over both; and this union is unfavourable to the inhabitants, as it enables the collector to prostitute the judicial power for the gratification of his avarice. Sir John Malcolm estimates, though not on any sure data, the revenue of Persia at three millions. According to Frazer, the amount varies with each successive sovereign, with the extent of his dominions, and with the fluctuations which have taken place from rebellions in the different provinces. The public income of Persia arises from the produce of crown or government lands, from a tax on land, varying, as is stated by Sir John Malcolm, from twenty to five per cent. according to the fertility of the land, and according to its vicinity to water, which is the great source of fertility in Persia. Frazer states that the land-tax amounts to from ten to five per cent. on the gross produce. Landed property in Persia may be comprised under the following heads: 1*st*, the crown-lands; 2*d*, those that are the property of individuals; 3*d*, those belonging to charitable or religious foundations; and, 4*th*, those granted by the king for military service. The uncultivated tracts, which form so large a portion of Persia, are not claimed as property; but every individual who constructs one of the subterraneous canals called *cannauts*, or who contrives to bring water to the surface, obtains a title to the land which he cultivates. The other titles are, inheritance, purchase, or a gift from the crown; and these rights are held sacred under all circumstances. There is, however, this peculiarity in the state of landed property in Persia, as in other eastern countries, that the ryot or cultivator shares with the proprietor in a common right to a certain portion of the soil, of which he cannot be deprived as long as he pays the customary rent. The proprietor has a title to one tenth of the produce, ascertained by measurement, either of the surface before sowing, or of the standing crop. When the proprietor obtains an artificial supply of water, he has, besides, a right to all that he can procure by its sale. In cases where the proprietor furnishes seed, labour, or cattle to the cultivator, he receives, in addition to his tenth share, a portion of the farmer's profits. The government-tax amounted at one time to one tenth of the produce, but with the increasing expenses of the state other irregular taxes were imposed, till they were at last converted into an additional tenth; the less fertile lands being, however, subjected to a smaller impost. But other irregular imposts still continued to be heaped upon the additional tenth, by the bad faith of the government, which imposts were altogether capricious and arbitrary, and now form one of the ryot's heaviest grievances. The other taxes are those on cattle, capitation taxes, transit and town duties on merchandize, and various other impositions which are quite uncertain and irregular. Lands held in fief, or in lieu of military or other service, pay no tax to government; the assignee being entitled to three tenths, which includes both the proprietor's rights and the government dues. When the assignment is given on the estate of another, it is merely the government-dues which are granted. Gardens near villages pay one fifth of their produce in kind, whilst melon-grounds, tobacco, cotton, and such like fields, pay in money according to a valuation of their produce. Horses, asses, cows, sheep, and goats, are all taxed, at the rate of one real, or 1s. 4d. for each horse, four fifths for asses and cows, one third for sheep and goats, and one sixth on the hire of bees. There is a capitation-tax, which sometimes presses heavily upon Armenians, Jews, and Guebres, the ancient fire-worshippers. The rate was in some cases four reals, or 5s. 4d., for a family, and sometimes eight reals. Shops and bazaars pay a duty of from two to twenty reals a year; and the tenant also pays in the proportion of from ten to fifty tomauns a year, the value of the tomaun being 11s. All merchandise is subject to a duty of five per cent. on entering the first Persian town, whether by land or sea, and to a variety of inland duties, which are levied at the different custom-houses without any rule or system, every governor endeavouring to extort all that he can. Smuggling is very commonly practised. No estimate can be formed of the *saaduraut*, or the irregular duties, which include every extraordinary expense of the government, the expenses of all travellers and strangers, those of all members of the royal family, or messengers on government business, the expense of transporting baggage, royal equipage, or presents, of repairing the roads and bridges, of furnishing troops for service, and the like; for all which it is understood, though the practice is often different, that the village or province shall obtain credit on the annual settlement of their accounts; so that these heavy exactions, resembling those of the king's purveyors in ancient Europe for the maintenance of his court and retinue when they were travelling, fall without redress on the poor ryots. The Persian king's order is, in like manner, grievously abused to the oppression and vexation of his subjects. Presents, fines, and confiscations, form a considerable item of Persian revenue. At stated times, such as the new year, the courtiers are expected to accompany their respects to the king with a large present of money, which amounts in some cases to 50,000, 60,000, and even 100,000 tomauns. Every one in any degree dependent upon the court endeavours to make up a purse on this occasion; and in lieu of money, goods, such as shawls, horses, jewels, and merchandise, are brought. The produce of this new-year impost is estimated at 1,200,000 tomauns. But there are various other lesser occasions for making presents, no suitor for favour or pardon being expected to approach the throne empty-handed; so that about 500,000 tomauns may be received in addition to the presents of the new year. The produce of the crown-lands Frazer estimates, though he admits, on uncertain data, at 989,000 tomauns. Every mode of tyranny and extortion is practised on the one hand by the collectors of the revenue, which is met by shifts and pretexts without number on the part of the tax-payer; "so that," says Frazer, "there is a continual struggle between the governor of a province and his myrmidons on the one side, and the villagers with their zabuts and ketkhodas (head officers) on the other; the former endeavouring to squeeze as much more as possible than their right from the latter, who strive, by every trick and invention, to avoid paying even that acknowledged right."[1]

The expenditure for which this revenue has to provide cannot be estimated from any authentic document. The chief expenses are the maintenance of the royal family, and the royal harem, which contains 300 wives, with a proportional number of slaves and servants, amounting to not less than about 1500 persons. The expense of the royal stud, including the baggage, camels, and mules, the retinue attending the royal march, the value of presents, namely, the khilauts or robes of honour, which are regularly given away, and which are seldom worth less than from 500 to 600 tomauns; the Cashmere shawls, swords, daggers highly ornamented, and horses with gold or silver harness; form a serious drain on the royal treasury; and to this may be added the maintenance of the household troops. All these expenses are heavy, and in general swallow up a large portion of the revenues, however ample. The superior officers of government are paid with the utmost parsimony, which proves in the end far more expensive than the most liberal salary, their scanty allowances being made up by peculation and extortion. The salary of a prime minister does not exceed a few hundred tomauns in the year, but it is made up to an indefinite amount by bribes, presents, fees, and speculations of various kinds. Sometimes an assignment on the revenue of a village is given in lieu of salary; the inhabitants being thus placed at the mercy of the assignee, who fleeces them without mercy, often to more than three times the regulated amount. All these unjust practices are well known to the king and his court, who wink at what they would find it impossible to prevent, and who also know that all the hoards of individuals are carefully watched by the spies and underlings of the court, so that these ill-gotten treasures may be made forthcoming at any time for the behoof of the monarch. The nobles, and especially the officers of government, are wretchedly poor, as well, indeed, as all the rest of the people; they are mostly all ruinously in debt. The mehmandar or officer of government, who escorted Frazer from Bushire to Shiraz, in describing his own situation, spoke openly of the "miserable system of extortion and parsimony practised by the king and rulers of the land;" and he was far from being the only one who uttered such sentiments, which, according to the traveller above mentioned, were in every mouth, and a common topic of conversation.

---

[1] Narrative of a Journey into Khorassan, chap. x.

There is no regular body of trained soldiers in Persia, but merely irregular levies, fitted for the species of warfare in which they are generally engaged. Every province ought to maintain a certain number of men, armed and mounted, and ready to take the field. This is the national force of Persia; the militia collected from the wandering tribes, and from the inhabitants of cities and villages, who are liable to be called out on any emergency, and, when on service with the army, or in distant garrisons, receive pay from government. They provide their own clothing, which is the common dress of the country, and their arms, consisting of a matchlock, sabre, and dagger. The number of this registered militia is estimated at 150,000 men. But recently all military duties have been neglected, and it would now be scarcely possible to muster the smallest appearance of an army. The inhabitants of Fars obtained an abatement of revenue, on the ground of their obligation to maintain a force to watch the movements of the British in the gulf; but not a single soldier could ever be seen by the British embassy in passing through that province; and any military display that was made was evidently by men suddenly called together from their regular occupations. No attempt was ever made to maintain a regular army, excepting by Abbas Mirza, governor of Azerbijan, and heir apparent to the throne; and whilst these troops were commanded and disciplined by English officers, they had every appearance of an efficient force, amounting to 20,000 men. But after the conclusion of peace with Russia, they were, from parsimony or improvidence, disbanded; it being considered as useless to give regular pay where no service was required. On the commencement of the Turkish war, the English officers, who could no longer be permitted to serve, were almost all dismissed; and a few sergeants only remain, who command and maintain the horse-artillery in a tolerably efficient state; but this corps, with seven or eight hundred Russian deserters, is the only serviceable part of the establishment. The prince has, besides these corps, wall-pieces, mounted on camels, which could only be efficient against Asiatic troops. His arsenal is, however, miserably furnished; and, unlike the arsenals of Europe, which contain such vast stores of ammunition, it is on a scale more suited to the shooting-closet of a private gentleman, than a magazine of state. When the army took the field against the Russians, only twenty-five rounds of ammunition were provided for each gun, and scarcely any supply was left behind, whilst the manufacture was proceeding on a scale the most pitiful. The levies furnished by the chiefs of tribes at the call of their sovereign form the most efficient portion of the militia, consisting entirely of cavalry, which, though somewhat degenerated, are still hardy and active, having preserved the habits and mode of fighting of their fathers. Their horses are active and strong, and in all respects suited to predatory warfare, to which indeed they are inclined by the prospect of plunder, the chief motive of their services; for if they are not engaged in active hostilities, they always return home during the winter.[1] The Persians assert that the king can command the services of 80,000 of these irregular troops; an assertion which is scarcely borne out by facts. Some provinces famed for their irregular troops serve as nurseries of the army. The land-tax of Mazanderan is chiefly paid in military service, and this province, including Astrabad, maintains nominally 12,000 foot and 4000 horsemen, ready at a call. But the fact is, that these troops are greatly dispersed amongst their own villages, and many of them have not a horse to show. The only permanently-embodied corps is the body-guard of the king, or the *gholauns*; but they have no regular organization, any more than the others, nor do they assemble and parade together. Their number amounts to from three to four thousand men; and they are chiefly distributed near the residence of his majesty in town, and attend him in camp, a certain number being always on duty. They are all mounted, their horses being found by government, and they are armed, as usual, with a matchlock or sword. Their pay varies from twenty to thirty tomauns in the year; though those of long standing, and of tried valour in the service, receive much more. These are frequently employed in affairs of great importance; often in the collection of the revenue, when they neglect no opportunity of extorting large sums. They consider themselves as gentlemen, though in the rank of soldiers. They are, some of them, the younger sons of nobility; and are for the most part bold and insolent debauchees, great swaggerers, with but little courage, tyrannizing over the weak, but respectful and fawning to those in power. Their name is a terror to the country, and their arrival in any quarter is deprecated as a serious misfortune, the people in some instances flying from the village at their approach. Frazer considered the unwarlike character of the Persian monarch as a great discouragement to the military service. He was cowardly, and remarkably avaricious; parsimonious in rewarding service, and jealous of any of his subjects acquiring military renown; so that a chief, when they were proposing an expedition against the Turcomans, declared his own feelings in very plain terms: "To what end," said he, "should I destroy these people? What thanks should I receive from Futteh Allee Shah? Perhaps to have my eyes put out."

Persia, from this view of her internal sources, must rank very low in the scale of nations, and would be quite unable to withstand any European power. During the war which so long raged between Great Britain and France, her alliance was eagerly courted by both these powers; by the former, in order to baffle the supposed schemes of Napoleon for the invasion of India, although it is extremely doubtful if any such were seriously entertained. France was equally eager for the friendship of this weak state. Great Britain lavished her gold on the Persian king, for which he gave his empty promises of friendship; and when France entered the lists with Britain for his coveted alliance, the king made the most of both; nor, as Frazer justly observes, was it his part to tell how valueless was the prize for which they each offered so high. The British statesmen, perpetually haunted with the terror of Bonaparte, were in dread lest a French and Russian army should make its way through Persia to India. But neither the cajolery of Great Britain, nor her bribes, would have enabled Persia to oppose so powerful an invasion of her territories, if it had been attempted. Her whole power would have been exerted in the defence of her dominions, even if Britain had not interfered; more she could not do though the whole wealth of the country had been poured forth before her king and his nobles. Most uselessly, therefore, on this, as on numberless other occasions, were the treasures of Britain squandered away to bribe this barbarous power to pursue a course prescribed to her, and which she would of herself inevitably have followed in her own defence; whilst the character of the country was lowered, by the humble, and even fawning, tone of the British in their official communications. Persian arrogance has been thus fostered; and the Shah has been encouraged to despise and deprecate the power and alliance of Britain, notwithstanding her profuse liberality.

[1] Sir John Malcolm's History of Persia, vol. ii. chap. xxiii.

Religion.

The ancient idolatrous religion of Persia was supplanted by that of Mahommed, which at an early period was propagated in Persia by the victorious Moslemins; and it has ever since continued the popular superstition of the country. But the Persians are of the Sheah sect, who consider Ali, the uncle and father-in-law of Mahommed, as his lawful successor in the caliphate, to which he was appointed by the Prophet; and Abubekr, Omar, and Othman, his actual successors, and reverenced as the caliphs by the Soonies, as nothing better than usurpers. It was this disputed succession which gave rise to these two hostile sects of Mahommedans. The doctrines of the former, namely, the Sheahs, have been for more than three centuries warmly espoused by the Persians, who vowed eternal hatred and war against all who profess the Soonie creed. The religion of Mahommed, amongst its other evils, is hostile to all improvement. It enjoins the destruction of infidels as an act of piety; intolerance thus becomes a duty; and hence the blind zeal and persecuting spirit which prevails in all Mahommedan states, and which breaks out into reproach, outrage, and often into extreme violence, against their Christian visitors. All knowledge is, according to this system, rejected, beyond what is found in the Koran; and the debasing influence of polygamy on the morals and manners of both sexes is calculated completely to poison all the remaining sources of social happiness. The baneful consequences of this superstition have been as deeply felt in Persia as in any of the surrounding states. The Persians have been thought by travellers to be less bigoted than their Turkish or Arabian neighbours. But though, from their lighter dispositions, they may not be so austerely rigorous in their religious observances, and may even converse with more freedom on religious subjects, from their intercourse with European Christians, who cannot be used with the same outrage as their own countrymen, yet, according to the testimony of Frazer, they are even more deeply prejudiced than either the Arabs or the Turks, who will not scruple, if they invite a Christian to their house, to eat with him from the same dish; whilst a Persian will provide a separate tray for him, and avoid, as much as he can, all contact. Europeans attached to the suites of ambassadors are admitted into the public baths; but a European travelling without a mehmandar or a government functionary would not be allowed any such privilege; and though European gentlemen, for a large bribe, are admitted in disguise, or in secret, into the mosques or holy places of pilgrimage, a poor Armenian or a Jew would as surely be put to death if found within the sepulchre of Imaun Reza or Fatima, or the great mosque at Shiraz, as within the mosques of Constantinople or Damascus. The fanatical influence of the Mahommedan religion has of late years, however, been modified in Persia, by the progress of a free-thinking and irreligious spirit, chiefly amongst the nobility, the merchants, and those who have resided much in foreign countries, and even amongst the priesthood, who frequently and openly, before their particular friends, deride the superstitious observances of the Mahommedan creed. The zeal of the early Mahommedans has also been cooled by many causes. The work of conquest, and the extinction or conversion of infidel nations by the sword, is at an end. The enthusiasm of the modern followers of the Prophet is no longer influenced by the practice of persecution; and the whole system has declined into a set of useless forms and ceremonies, which, mingling with all the common affairs of life, have degenerated into a customary routine, without any appearance of reverence, and being in reality a mere mockery of religion. "The name of God," says Frazer, "in various forms, is called upon on the most trivial as well as the most important occasions. However men may be occupied when the set hour of prayer arrives, those who choose to observe it merely turn aside from the rest, still laughing, perhaps, at the last ribald jest, and commence their invocation of God. During the intervals they continue their conversation, scold or give orders to their servants, comb their beards, and adjust their persons, frequently interrupting their expressions of praise or of devotion, to give vent to the most trifling, or perhaps the most obscene remarks."[1] The observance of these empty forms is nowise connected with morality, except to degrade it; the most zealous Mahommedans, even those who have made the pilgrimage to Mecca, being frequently noted for the impurity of their lives. From this and other causes, the Mahommedan religion, which once kindled so vast a commotion in the world, is now on the decline; and the followers of the Christian faith have made such progress in all useful knowledge, that Mahommedans are fain to become the imitators of their fashions, as, by a gradual transition, they may also yet be of their purer faith.

In a state of society such as that which prevails in Persia, we can scarcely look for any great progress in literature, science, or the arts. With the Mahommedan religion was introduced all the Arabian learning of the seventh century. But the Persians have not improved this original stock; on the contrary, it has gone to waste in their hands; the light of science is nearly extinct, and their literature consists chiefly in their poetry and tales. They delight in tales, fables, and apophthegms, which Sir John Malcolm considers as the consequence of their despotic government, where knowledge must be veiled in order to be useful, as the direct truth would wound a despot's ear. It is in poetry that they are said chiefly to delight and to excel; though the hyperbolical style and the wild tales of the East would scarcely suit the fastidious taste of European critics. The merits of Persian poetry have been very differently estimated. Sir John Malcolm, admitting its extravagance and hyperbole, still praises its tenderness and beauty; and many passages are said to breathe all the sweetness of pastoral poetry. Ferdousi is one of their greatest epic poets, whose poem (the *Shah-nameh*) is historical, in which, according to Sir John Malcolm, "the most fastidious reader will meet with numerous passages of exquisite beauty. The narrative," he adds, "of this great work is generally very perspicuous; and some of the finest scenes in it are described with simplicity and elegance of diction." In the opinion of Persians, this poet excels in his descriptions of the combats and battles of his heroes; but to those whose taste is offended with hyperbole, the tender parts of his work will have most beauty, as they are freest from this characteristic defect of eastern writers. Nizamee, who celebrates the exploits of Alexander the Great, is considered as ranking next to Ferdousi; and the subject affords ample scope to his genius and his powerful imagination. Amongst the didactic poets Sir John Malcolm assigns the next rank to Sadi, who is a moralist as well as a poet, his works abounding in the most useful lessons of prudence and morality, and exhibiting a rare union of fancy, learning, urbanity, and virtue. The Musnavel of Jellal-u-Deen, the poems of Jami, and the odes of Hafiz, are amongst the most popular effusions of the Persian muse; but the names of Rudiki, Anveri, and several others, are nearly of equal rank; and some modern writers also have attained to great eminence. "Many of these poems," says Sir John Malcolm, in his excellent History of Persia, "are remarkable for harmony of numbers and luxuriance of imagination, but they all abound with the most extravagant and hyperbolical passages; and the enraptured dreams of their visionary authors can only be esteemed beauties by men whose imaginations keep pace with that of the poet, whom they deem inspired, and whose most obscene lay is often considered by their enthusiastic admirers as the gleaming of a sublime knowledge, which is far beyond the comprehension of the profane and unenlightened. Many discussions have arisen regarding the real and mystical meaning of the writers of this class, and particularly of Hafiz, whose odes are chanted as songs, to excite the young and dissipated to pleasure, and recited as hymns, to remind the old and devout of the rapture of divine love." The Persian poets excel in songs and odes, which are chiefly composed on local subjects, and are tender and passionate. Satirical effusions are not so common; though the verses of Ferdousi on Mahmood of Ghizni are remarkable for the bitter feelings which they express. There is a satirical poem, by an unknown author, on the passion of avarice, which is extremely humorous and satirical. The Persians are enthusiastic in their taste for poetry; and the meanest artisans can read or repeat the finest passages of their most admired writers. Sir John Malcolm mentions that his servants were familiar with Persian poetry; and when at Ispahan, he was surprised to hear a common tailor, who was repairing one of his tents, entertaining his companions with some of the finest mystical odes of the poet Hafiz. Even the rude and unlettered soldier will leave his tent to listen to songs of love or to a tale of war. The art of printing is unknown in Persia; and beautiful writing, which is carefully taught in the schools, is considered as a high accomplishment; those who excel in it ranking with the literary class. They are employed in copying the works of authors; and a few lines written by a celebrated penman are often sold for a considerable sum. By the invention of printing a great moral revolution has been brought about in the state of society; and a want of inclination to profit by this great improvement indicates extreme apathy and ignorance on the part of any nation. Yet almost all the tradesmen and many of the mechanics in Persia have received some education. Schools are established in every town and city, at which the poorest children are instructed, at fees sufficiently reasonable, in the rudiments of the Persian and Arabic languages. The pupil, after he has learned the alphabet, reads, as a religious duty, the Koran in Arabic, next some fables in the Persian language, and, lastly, he is taught to write a legible hand, which completes his education. Unless amongst those who follow a studious life, and thus put in practice what they have learned, these lessons are in many cases forgotten. Yet this course of study, superficial as it appears, improves the habits, and introduces a refinement of manners amongst the scholars, which is unknown to their ruder countrymen. No proper encouragement, however, is given to schools; nor can it be expected that a grasping, despotic, and rapacious government, like that of Persia, should be any way anxious for the education of its subjects. The literary men are numerous. They pursue their studies till they are entitled to the name of Moollah, and to all the honours of a Persian college, though they are not classed with the priesthood. They follow various occupations. To the studious and literary classes a very high rank is assigned. An eminent historian, astronomer, or poet, is highly honoured, and has a place of distinction assigned him in every company which he honours with his presence; and this as much for his social qualities as for his supposed talents as an author. The conversation of these persons, replete with anecdotes and information, amuses and instructs; and even the pretenders of this class, who are numerous, possess agreeable manners and a ready wit. Living by their wits, they are generally noted flatterers, dwelling especially on the wonderful deeds and character of the king or his principal nobles, for which they are well paid. Others write panegyrics on all who pay them for it, either in money or in hospitality. They also make epigrams to amuse their patrons, or recite the finest passages of the national poetry. But the great majority are poor, seeing that their numbers have outgrown their employment. Every person with a moderate education may assume the name of a poet, and the merest rhymer receives some additional respect upon this account. A swarm of students is thus produced, who pass their useless lives in indolence and poverty. Ispahan in particular abounds with these literary mendicants; and from its colleges, and those of Shiraz, issue a crowd of vagrant poets, who lie in wait for men of rank and wealth, or for any stranger from whom they expect a reward. Sir John Malcolm, in his first visit to Persia in 1800, was addressed by one of these poets; and though he was repeatedly told that the stranger could neither comprehend his lines nor relish such compositions, he persevered in his purpose, telling some appropriate story, until he extorted his due meed, not of praise, but of money.

---

[1] Narrative of a Journey into Khorassan, chap. ix.

In music and painting the Persians have made no progress. They consider music as a science, but they have nevertheless made no further advances in it than the Indians, to whom they are supposed to owe all the knowledge which they possess. They have a gamut and notes, and a melody that is adapted to various strains; and they sing to the accompaniment of warlike instruments, of which they have a number. Their strains are often pleasing, but they are always monotonous. They are equally backward in the art of painting, in which they have advanced but little within the last three centuries. They use the most brilliant colours, and in portrait-painting they usually succeed in taking likenesses; and in some of their lesser drawings, which are highly glazed, and painted on wood, they also display industry and taste. But they are entirely unacquainted with the rules of perspective or of just proportions. The despotic and unsettled government arrests all improvement; and in the fine arts the existing race have not advanced one step beyond their forefathers, as appears from the figures in the palaces at Ispahan, executed in the reign of Shah Abbas, and equal to any of their modern productions.

Mathematics, astronomy, and geography.

In science the Persians have advanced no farther than in the arts. Their knowledge of mathematics or astronomy is very limited; and the latter science is chiefly studied for the sake of judicial astrology, in which the whole nation, from the king to the peasant, evince the greatest faith. Their notions of the forms and motions of the heavenly bodies, and the shape and surface of the earth, are borrowed from Ptolemy; and though some efforts have been made

Persia.

to instruct them in the Copernican system and Newton's demonstrations, prejudices are too firmly rooted to be dispelled, except by time. Of geography they do not understand the first principles; for, independently of their error regarding the figure of the earth, they know little of its surface, even of that which lies within their view; nor could their knowledge of surveying enable them to lay down any portion of it with exactness. There cannot be a stronger proof of the ignorance which prevails than the eagerness with which all classes seek the aid of astrology. Any one who can take an altitude with an astrolabe, or knows the names of the planets, with a few technical phrases, and understands the astrological almanacs, considers himself as quite adequate to offer his services to all who consult him; and nothing of consequence is transacted, especially by the great, without consulting the stars. A new dress must be put on, or a journey must be commenced, at the lucky or unlucky moment. The prime minister of Persia seeing Sir John Malcolm smile at the idea of his seeking the propitious moment for putting on a new dress, observed, "Do not think, Captain Malcolm, I am such a fool as to put faith in all this nonsense; but I must not make my family unhappy by refusing to comply with forms which some of them deem of consequence." Some years ago a Persian ambassador was about to proceed to India, when he was informed by his astrologer of a most fortunate conjunction of stars, not likely to occur again for some months. He accordingly set out, though the ship was not ready to sail; and because it was discovered by the astrologer that he could not go out of his door, on account of an unfavourable constellation exactly opposite, he broke through the wall of his house, and four or five other walls, before he and his men could reach the street. Many of the astrologers who practise this art are with reason thought to be more knaves than fools, and flatterers of those who consult them, in order to fleece them of their money.

As the science of astronomy is thus rendered subservient to astrology, so chemistry is followed for the sake of alchemy, a favourite pursuit of the learned, whose avarice is stimulated by the hope of discovering the philosopher's stone; that absurd chimera of a barbarous age, long ago exploded amongst the sciences of Europe. The alchemists make their experiments in the profoundest secrecy, that they may themselves engross the whole benefits of the wonderful discovery which they expect to make; and whether they may be themselves deceived, certain it is they deceive others, and practise the most serious frauds on the credulous and the wealthy. Of medicine and surgery the Persians are thoroughly ignorant, and, when they are ill, become the prey of quacks, who rob them of their money, and often of their health. They are entirely ignorant of anatomy and the circulation of the blood. They have an arbitrary theory, by which they classify all diseases under four heads, viz. hot, cold, moist, or dry; and the great principle on which they proceed is, that the remedy must be of an opposite quality to the disease; dry remedies being applied to an illness occasioned by moisture, and cooling medicines to hot diseases. To this practice they are so bigoted, that, with all their respect for European physicians, they dislike any prescriptions that contradict this paradox. Inoculation for the small-pox, though it is known, is seldom practised, though whole towns are often threatened with depopulation by the ravages of that dreadful disease. Mr Jukes, who accompanied Mr Frazer into Persia, was remarkably anxious to introduce the practice of vaccination: for several years his efforts were unremitted; but they were defeated, fully as much from the cruel indifference of the government to the good of their subjects, as from their prejudices. This great and important discovery appeared to give the most lively satisfaction to the great men of the country; but that interest in the happiness of the people, and those feelings of humanity, which are seen in Europe, are entirely wanting in Persia; and hence all attempts to introduce vaccination amongst the people were finally abandoned. The practice of physic in Persia is mere quackery, for which all the knowledge necessary is that of the qualities and effects of a few simples; and hence a grave air, and a few lucky cures, often brought about by the temperate habits of the patient, complete the fame of a physician. The gains of the physician are, however, trifling. The priests and astrologers succeed better; their art is more suited to the taste of the inhabitants; and it is only in cities and towns that there are regular physicians. Those who dwell in tents are generally attended by an old man or woman, and rely more on superstitious charms than on medical remedies. One of these charms consists in laying a few pieces of bread covered with oil upon a rock, as an offering to a saint. There are many quacks in Persia, as in other countries, who pretend to cure all diseases, and who boast a hereditary right to certain nostrums. The chiefs of a mountain tribe pretend to cure the ague by tying the patient up by the heels, and scolding and beating him severely, to prevent the access of the cold fit.

Mann and toms

The Persians are remarkably ceremonious in their intercourse. They receive the visit of a superior by rising hastily and meeting him at the door of the apartment; of an equal, by rising and standing erect; of an inferior, by only making the motion of rising. The apartments are not so luxuriously furnished as in Turkey. The sofas and easy pillows of the latter country are not known in Persia, where the seat is on a carpet or mat, without any soft support on either side, or any thing except the hands, or the accidental support of a wall, to relieve the galling posture of the legs. The fashion in presence of a superior is to sit upon your heels, as they are tucked up under your hams, after the manner of a camel. The misery of this posture in its politest form can scarcely be described, according to Morier, who thought he had attained to great perfection in the Persian fashions when he could sit cross-legged like a tailor; and Sir R. K. Porter mentions, that after a Persian entertainment at which he was present, he was so tired with the awkwardness of the posture, that he could scarcely rise when the meal was finished. The length of time during which a Persian sits untired upon his heels is to an Englishman quite extraordinary. He will remain half a day, and sometimes he will even sleep, in this posture. They never think of changing their positions; and are as much surprised by the locomotive dispositions of the Europeans as we are by their habits of rest. They impute their walking to and fro, their sitting down, getting up, and moving in every direction, to the influence of some evil spirit; and sometimes they think it is the European mode of saying prayers. Morier gives a curious account of a visit of ceremony to the governor of Bushire, and also of a dinner at which he was entertained. They made their visit on horseback, according to the custom of the country, though his tent was not a stone's throw from theirs. They were met by one of the officers, with an escort of ten men, who made their obeisance; and when they arrived at the door of the khan, where they were most graciously received, having pulled off their boots and shoes, a necessary part of the ceremonial, they were finally accommodated with chairs prepared for them. The tent was extremely neat; and in the interior there was a clean little recess, closely covered with carpets, and lined with the finest chintz, adorned with a broad fringe. They were then entertained with *kaleoons* or water-pipes, and with coffee and sherbets; and the whole entertainment concluded with a course of sweetmeats, consisting of almonds, pistachio-nuts, with a paste of sugar, and other sweetmeats, of which the Persians are immoderately fond. The fastidiousness of the English visitors was, however, sorely tried by the ill-timed complaisance of two lusty attendants, who broke the sweetmeats with their fingers, and blew off the dust of the fragments with their mouths. At dinner they sat on the ground in the position already mentioned, which was rendered more difficult than can be conceived, by the inflexibility of their knees, contracted from long habit; and the khan, in pity to their evident distress, begged them to extend their legs at full length, which they, however, declined, in compliance with the Persian fashion. After being treated to pipes and coffee, dinner was called for. On the ground was spread a fine chintz cloth, which completely covered their legs, and had been so long unchanged, that it was dirty from the fragments of former meals, and emitted no very savory smell. But the Persians never change it, from an idea that it brings ill luck. Sherbets were first served up upon fine china bowls to each guest, two made of sweet liquors, and another of an exquisite species of lemonade. There were, besides fruits ready cut, plates with sweetmeats and confectionery, and smaller cups of sweet sherbet. The pillaus succeeded, one of plane rice, another made of mutton with raisins and almonds, and a third of fowl with rich spices and plums; also various dishes with rich sauces, and over each a tincture of sweet sauce, which is a great article in Persian cookery. The Persians eat comfortably in their fashion, advancing their chins close to the dishes, and commodiously scooping the rice or other victuals into their mouths with three fingers and the thumb of their right hand. But when the English guests attempted to approach the dish, they were impeded by their tight-kneed breeches, and all the ligaments and buttons of their dress; and in the course of their eating, fragments of meat and rice fell through their fingers all around. The dinner was carried off in the same state in which it was brought; the servant who officiated dropping gracefully on one knee as he carried away the trays, and passed them over his head with both his hands to another lacquey, who was ready behind him to carry them off.

It is a singular trait of Asiatic manners that so great a proportion of the people still retain the vagrant habits of the pastoral life. For this purpose the wide wastes of Khorassan, varied with spots of fertility, are well adapted; and the pastoral tribes are accordingly found chiefly to border on this district, which has long been the debateable ground between several great monarchies, where their rival chiefs contended for victory in fierce and bloody wars; and on these occasions the wandering tribes are enlisted on one side or the other. Thus they are inured to blood and to pillage, and contract habits which have been strengthened by time, and have at last become interwoven with their whole pursuits and character. They often attack surrounding states, carry off the people, and sell them for slaves; and most of the wandering tribes of Turcomans being Soonies, who have sworn eternal hatred to the Persians, who are Sheahs, thus add religious hatred to all their other incentives to murder and pillage; so that their character is described as ferocious and blood-thirsty in the extreme. To the north of Khorassan there are various tribes of Turcomans, who, occupying the country behind the Elburz and the steppe of Kaurezm, pour from their deserts upon the surrounding and cultivated districts, plundering villages and caravans, with every circumstance of atrocious outrage. The old, the feeble, and the helpless, are murdered on the spot; those who are fit for labour are carried into slavery; and whole districts of country are left desolate. From the east other tribes equally barbarous make inroads into Persia, and carry away their captives to the slave-markets of Khyvah and Buckharia; and on the south and east are found the wild Ballooches, who formerly plundered and murdered, but now, preferring their avarice to their cruelty, carry their prisoners to the slave-merchants who frequent the great northern markets. The Afghan, also, though not naturally cruel, "assumes," says Frazer, "in this ominous neighbourhood a fierce character, and adds to robbery and plunder the crime of murder." By these dreadful inroads a considerable portion of the country to the north and east is laid waste; the terror of these tribes is spread far and wide; and their depredations have become more formidable in proportion to the corruption and increasing weakness of the Persian monarchy. These tribes vary considerably in their physiognomy. The Tuckehs, who occupy the country behind the Elburz Mountains, bordering on the Caspian Sea, are tall, stout, and well made, and have all the Tartar features, namely, the scanty beard, the small eye drawn up at the corners, the high cheek-bones, and the small flat nose. Some, on the other hand, have handsome features, rather resembling those of the Asiatics than of the Europeans. The arms used by these tribes are chiefly the sword and the spear. They are dexterous in the use of the sword, which is curved in the Persian fashion, and very sharp. Several of the tribes use bows and arrows. They have very few fire-arms; only such as they have taken from travellers whom they have plundered.

Antiquities.

Persia, the seat of learning, of wealth, and of improvement, whilst the greater part of the world had scarcely emerged from barbarism, might naturally be expected to abound in the precious relics of ancient art; and although many such memorials have perished amidst the ruthless devastations of war, to which this and other Asiatic countries have been exposed, yet numerous monuments of taste still remain. Of these, the ruins of Persepolis belong to the earliest era of Persian history. It was in this city, which they took a delight in improving and embellishing, as the great metropolis of the East, that Cyrus and his immediate successors resided. It has for centuries presented only a scene of decay and ruin. The most remarkable remains in Persepolis, or, as it is called by the natives, Tackt-i-Jemsheed (the throne of Jemsheed), are the Chehelminar or the forty columns, which are situated at a small distance to the north of Shiraz. Sir R. K. Porter recognised in these ruins, *en masse* as well as in detail, a strong resemblance to the architectural taste of Egypt; and he conjectures that some of the architectural ornaments may have been partly brought from that country by the Persian monarchs, as trophies of their victories. These magnificent remains appear to be part of the great castellated palace of Darius, which was set on fire by Alexander whilst he was under the influence of intemperance. They are placed as if in an amphitheatre, on a fine plain, enclosed by semicircular mountains. The terrace on which the ruins of this immense royal citadel or palace is placed, is of a very irregular shape, and it faces the four cardinal points. The extent of the southern face, according to the measurement of Sir R. K. Porter, is 802 feet; of the northern 926, and of the western 1425. "The strength and beauty of its construction," says the same traveller, "cannot be exceeded. The steep faces of the rocky terrace are," he continues, "formed of dark-gray marble, cut into gigantic square blocks exquisitely polished, and, without the aid of mortar, fitted to each other with such closeness and precision, that when first completed the perfected platform must have appeared as part of the solid mountain itself."[1] The level on which the buildings had been erected has become exceedingly uneven, from the accumulation of fallen ruins; and the height of the wall appears to have varied from twenty-five to fifty feet, according to the inequalities of the ground. The exterior wall is built of black stones much harder than marble, finely polished, and of such a prodigious size, that it is difficult to conceive how the workmen, without the aid of machinery, were able to move them. The only access to the summit of the platform is by a double flight of stairs of a very gentle ascent, on its western side. There are fifty-five steps, each step being three and a half inches in height, formed of blocks of marble so large that each of them is cut into ten or fourteen steps. The first flight of steps leads to an irregular landing-place of thirty-seven feet by forty-four, from which springs a second double flight of forty-eight steps, which terminate on the ground level of the platform in a second landing-place, occupying sixty-four feet. "The beauty and ease of the ascent," says Sir R. K. Porter, "will be readily understood when I mention, that I invariably rode my horse up and down them, during my visits to their interesting summit." On reaching the platform, the first objects that arrest the attention of the traveller are the lofty walls of an enormous portal, the interior faces of which are sculptured into the colossal forms of two immense quadrupeds, resembling bulls, which are elevated on a pedestal five feet in height. The heads of the animals are entirely mutilated, so that Frazer says it is impossible to determine what species they were intended to represent. Round their necks collars of roses are executed with critical nicety; and over the chest, back, and ribs, short curling hair, cut with that peculiar correctness and delicacy of chiselling which Sir R. K. Porter states to be a distinguishing characteristic of the ancient Persian sculpture. The wall that forms one side of this magnificent portal is five feet in breadth, twenty-one feet in length, and thirty feet in height. The one wall is distant from the other about twelve feet, and the space between is flagged with beautifully-polished slabs from the neighbouring rock.

---

[1] Travels in Persia, Georgia, &c. vol. i. p. 583.

Eastward, at the distance of twenty-four feet in a direct line from the portal, once stood four magnificent columns, of which only two now remain. Their capitals are singularly beautiful. At the distance of twenty-four feet is a second portal, exactly resembling the former, only that it is eighteen feet instead of twenty-one in length. Its inner sides are adorned with similar sculptures. But the animals here represented are of a gigantic size, and of a monstrous formation; the body and legs of a bull, with similar trappings to those already described, and enormous wings, the feathers of which are exquisitely cut. The heads of the animals, though greatly defaced, show the faces of men; the countenance has a cast of deep gravity; and a long and carefully curled beard adds to the general majesty. The head is adorned with a diadem, on both sides of which horns are represented winding from the brow upwards towards the front of the crown; the whole being surmounted by a sort of coronet, formed of a range of leaves like the lotus, and bound with a fillet beautifully carved in roses. This symbolical representation has long been a subject of speculation amongst antiquaries, and its meaning still remains a mystery, notwithstanding the many ingenious conjectures to which it has given rise.

Between the right of this portal and the magnificent terrace that supports the range of columns from which it takes its name, there is an area of 162 feet, in which is a cistern hewn out of the solid rock, in dimensions eighteen feet by sixteen. The approach to the terrace is superb, consisting of a double staircase, covered with the most beautiful decorations, and projecting considerably before the northern face of the terrace, which is 212 feet in length. At each extremity, east and west, rises another range of steps; and about the middle, projecting from it eighteen feet, appear two smaller flights, rising from the same points. The extent of the whole range, including a landing-place of twenty feet, amounts to eighty-six feet. The ascent is extremely gradual, each flight consisting of some thirty low steps, four inches in height, fourteen in breadth, and sixteen in length. The whole front is covered with sculptures so thickly that the eye is bewildered amid the various groups. They consist chiefly of figures and emblematical devices. The figures seem generally to be habited like royal guards or other attendants, clothed in long robes, with fluted flat-topped caps, carrying shields on their left arms, and wearing a sort of buskins, between the sole of which and the foot a small substance is introduced, to raise the height of the wearer. Others appear as if they were taking their part in solemn processions, bearing votive offerings, and leading animals of different sorts. Chariots are also seen drawn by different animals. These sculptures are executed with a nicety of detail which gives them a historical interest, as they mark with accuracy the costume of the time and the people, and the form and variety of the armour used at different periods. On these sculptures is also represented a fight between a lion and a bull or unicorn; Sir R. K. Porter greatly commends the fire, beauty, and truth, as well as the natural proportions, with which these figures are drawn. A particular account of the other sculptures will be found in the work of the above-mentioned traveller; and his descriptions are accompanied by drawings, which are extremely curious and interesting.

But the most splendid division of the ruins is the magnificent colonnade, which occupies the terrace, and which, having survived the devastations of war and the wreck of empires, remains on the desolate plain a most impressive image of departed grandeur. The terrace upon which these pillars stand stretches north and south 350 feet, and from east to west 380 feet; the greater part of the intervening space being covered with broken capitals, shafts of pillars, and numerous fragments exquisitely sculptured. There were formerly four divisions of columns, namely, a central group of thirty-six pillars, with two rows of six each on either side, as well as in front, in all seventy-two columns. Of the division in advance only one is now standing. About thirty-eight feet from the western edge of the terrace appears the second double range of columns, of which only five rows remain. The distance is 268 feet to the corresponding eastern rows, of which only four now remain. At a distance of sixty feet from the eastern and western colonnades stood the central range of columns, to the number of thirty-six; but of these no more than five remain entire. The three exterior double rows of columns are of uniform architecture, and described by Sir R. K. Porter as being perfectly beautiful. "I gazed on them," says he, "with wonder and delight. Besides the admiration which the general elegance of their form and the exquisite workmanship of their parts excited, I never was made so sensible of the impression of perfect symmetry, comprising that of perfect beauty also. The total height of each column is sixty feet, the circumference of the shaft sixteen feet, and its length from the capital to the top forty-four feet. The shaft is finely fluted in fifty-two divisions: at its lower extremity begins a cincture and a torus; the former two inches, the latter one foot, in depth. From thence devolves a pedestal, in form of the cup and leaves of a pendant lotus. It rests upon a plinth of eight inches, and measures in circumference twenty-four feet six inches; the whole, from the cincture to the plinth, comprising a height of five feet ten inches. The capitals which remain, though much injured, suffice to show that they were also surmounted with a double demi-bull. The heads of the bull forming the capitals take the directions of the faces of the respective fronts of the terrace; and I think there can be no doubt that the wide hollow between the necks received a beam, meant to support and connect an entablature, over which has been placed the roof." The dimensions of the central pillars are the same as those of the others, only that they are fifty-five feet in height, whilst the others are sixty feet. "Their shafts," says Sir R. K. Porter, "which are fluted like the others, are about thirty-five feet in length; but the capitals which surmount them are of quite a different character, being of the same description with that I noticed in the great portal where the crowned and winged bull is so conspicuous an object. The two lower divisions of the capital (it being of a triad form) are evidently constructed of the hollowed lotus. The upper compartment has only two volutes. The middle compartment, which is one division of lotus, appears to have had some extraneous body introduced into the opening between it and the lower compartment of the flower; and the angular and unfinished state of that side of the capital seems to testify the same. Here then the connecting line must have been whence the roof could spring."

The nearest building to the palace of the forty pillars occupies a space of a hundred and seventy feet by ninety-five, and it is approached by a double flight of stairs, which are almost in complete ruin; but from the fragments it appears to have been adorned with sculptures, resembling the royal guards and other figures. The side to the east is so choked up with ruins that no corresponding trace of stairs can be found. To the south the whole face of the terrace which supports this building is occupied with another superb flight of steps, which terminates in a landing-place forty-eight feet by ten. Its front is divided by a tablet bearing an arrow-headed inscription, on each side of which are seen spearmen of a gigantic stature. There appear to have been also other apartments with lofty entrances, composed of four solid upright blocks of marble of a colour nearly black, within the portals of which are bas-relief figures of two guards sculptured on the sides of the walls, besides various other figures, one of a monarch clad in royal robes; whilst in other parts there are representations of single combats between a man and a lion, a griffin, or some other imaginary creature. In another division of the same building may be seen a variety of inscriptions, cuneiform, Cuphic, Arabic, and Persian. Still farther to the southward appear other elevations or terraces, covered with vast masses of ruin, under which scarcely any traces of the original structure can be discovered; but here may be seen the remains of colonnades of elaborate sculpture. From the extremity of the eastern colonnade on the terrace of Chehel Minar is an expanse of 315 feet, the plain of which is interrupted by an immense pile of ruins, which has the appearance of having been heaped up for centuries, and which Sir R. K. Porter conjectures to cover a division of the palace answerable to that immediately to the south, and containing, as he supposes, the banqueting chambers and other apartments; and this conjecture he supports by many special reasons and learned authorities. South of this is another terrace, on which he supposes that there stood those portions of the palace in which the monarch resided. Here are the bases and plinths of pillars, and fragments of beautiful sculpture, scattered about. The ponderous door-ways and huge marble frames are yet in their places; they are of the finest workmanship, and are adorned with sculptures and figures such as those which have been already noticed, and of which our limits do not admit of a more detailed description. A considerable way north from the columns stands a structure which is next in extent to the Chehel Minar, or the palace of the forty pillars. It is a perfect square of 210 feet on each side, and is entered by two door-ways on each side, and by a grand portal thirteen feet in width, whilst the others are only seven. These are all richly adorned with sculptures, representing scenes of state or of royal parade, or emblematical figures of lions and imaginary animals.

Among other remarkable antiquities of Persia, the tombs, supposed to be those of her ancient kings, namely, Cyrus and his posterity, have attracted the particular attention of travellers. These excavations or tombs are generally cut out of the solid rock. About 500 yards eastward from the Hall of Columns, in the face of the mountain, is found a niche seventy-two feet in breadth by a hundred and thirty feet in height, divided into two compartments, and covered, as usual, with sculptures of non-descript animals, royal personages, and symbolical figures. Three quarters of a mile southward from Tackt-e-Jumsheed, a tomb was discovered by Niebuhr, and visited by Morier, which seemed to have no entrance, from which he supposes that those receptacles for the dead were entered by subterranean passages. The sepulchres of Naksh-e-Roostum, which have been visited by various European travellers, are also very curious. There are four excavations cut out of the perpendicular cliff, at the height, according to Sir R. K. Porter, of sixty feet from the ground. The one he examined, and to which he was drawn up by ropes, consists of an excavation in the solid rock of about fourteen feet, in the form of something like a Greek cross. The length of the cave, which forms the whole tomb, is thirty-four feet, and the height nine. It is adorned, like all the other ancient monuments, with a variety of richly-sculptured figures of men and animals, and emblematical devices. There are likewise numerous remains of antiquity in the plains of Mourghab, forty-nine miles north-north-east of the ruins of Persepolis, and probably belonging to the same era, which are fully described by Morier and Porter. The most remarkable of these is the supposed tomb of Cyrus; an interesting monument, of which the latter writer gives an account with his usual accuracy. It is surrounded by other ruins, which bear traces of the same antiquity, as they contain numerous inscriptions in the ancient arrow-headed character.

The sculptures on the mountain called Be-Sitoon are very curious, and have attracted the particular attention of travellers. This mountain, or rather abrupt precipice, is the termination of the rugged ridge that bounds the plain of Kermanshah on the north. It is 1500 feet in height, and the lower part has been smoothed to the height of 100 feet, and to the breadth of 150, leaving a projection both above and below, the latter sloping gradually in a rocky terrace to the level of the ground. No relics of any column have ever been found here; and hence the name Be-Sitoon, "without pillars." Just over the fountain-head of a beautifully clear stream, which bursts from the mountain about fifty yards from this rocky platform, are seen the remains of an immense piece of sculpture, so greatly defaced that no continued outline can now be made out; but by close examination the rude forms of several colossal figures may be traced. The principal cause of the mutilation seems to be that additions have been made to the original. In one place a Greek inscription has been introduced, and has, in its turn, been erased to make way for one in Arabic. Those rude sculptures are generally supposed to be of high antiquity, some referring them to the age of Semiramis. Above these appears an interesting piece of sculpture, containing fourteen figures, one of a king trampling on a prostrate body, probably of some of his captives. He has a diadem and all the other badges of sovereignty; and a row of nine persons having their hands bound behind them, and being themselves bound together by a cord round their necks, are seen approaching him in a suppliant posture, and with a dejected expression. Sir R. K. Porter supposes, apparently not without reason, that these ten persons, including the one under the feet of the monarch, represent the ten tribes which were carried into captivity; and that the design of the sculpture, which is executed in a style not inferior to any at Persepolis, is to commemorate the final conquest of Israel by Salmanaser, king of Assyria and the Medes. Above the head of each individual is a compartment with an inscription in the arrow-headed writing, probably descriptive of the design of this sculpture, and the personages contained in it. Hitherto, however, the learned in Europe have not been able to decipher this ancient writing; and hence the meaning of these and many other ancient monuments must still remain concealed under the mysterious veil of these unknown characters.

There are other antiquities in Persia that belong to the later period of the Sassanian dynasty, of which it may be proper to give here a brief notice. The most remarkable of these monuments are the sculptures at Tackt-i-Bostan, or the throne or arch of the garden. The mountain in which these are seen forms part of the chain of the Be-Sitoon; and, like it, is craggy, barren, and of the most rugged aspect. A remarkably clear stream bursts forth from the base of this mountain, and just over its source a bas-relief presents itself; and a little onward a flight of several hundred steps is found cut in the nearly precipitous cliff, finishing abruptly in an extensive ledge or platform. Beneath this platform are situated two arches, the largest of which is twenty-four feet in width, and twenty-one in depth. Above the sweep of the arch the face of the rock has been smoothed for a great distance, and also on each side; and on this surface there are two upright entablatures, containing an exquisitely-finished ornament of foliage, in the Grecian taste. Round the bow of the arch runs a double border, terminating in the Sassanian royal streamers. Over the key-stone of the arch is a crescent, supported on each side by the same regal insignia. Two gigantic female figures with wings appear hovering over the curves of the arch, and both extend their hands towards the crescent, each holding a diadem with a rich clasp, and waving ribbons, the usual emblems of the Sassanian dynasty. The inner face of the excavation is divided into two compartments, the upper containing three figures, on the left a female with a royal mantle and collar, and crowned with the peculiar diadem of the Sassanian princes. The gorgeous habit of the central figure, and the pointed diadem on his brow, with wings on each side that twist round the crescent surmounting the diadem, within which rises a globe, and the double waving streamers, proclaim him to be of royal dignity. He wears a short robe embroidered with pearls, a breast-plate of the same costly materials, and loose trousers over his ankles; and his left hand rests upon a sword, which, along with the belt that binds it, is covered with pearls. The figure to the right also wears a crown, but without the wings, the crescent, and the globe of the central figure. To this figure he is in the act of presenting a diadem, which the open hand of the monarch appears ready to grasp. These figures are all elevated upon rich pedestals. The lower compartment contains a colossal equestrian figure in alto-relievo, clad in a shirt of mail beautifully carved, and falling nearly as low as the knees. There are here traces of a Greek and of a Pehlavi inscription, both illegible. On the other sides are delineated a boar and a stag hunt, in the minutest detail.

The second arch is nine feet in width and twelve in depth. It contains, in the back of the recess, only two figures, similarly habited with the others, having the balloon-shaped cap, curled hair, and rich robes. On each side of the figures are found two inscriptions in the ancient Pehlavi character and language, which have been deciphered by the singular ingenuity and learning of the French academician De Sacy, and are as follow. The first inscription runs thus: "This is the figure of the adorer of Ormuzd, the excellent Shapoor, king of kings, of Iran and An-Iran, celestial germ of the race of gods, son of the servant of Ormuzd, the excellent Hoormuz, king of kings, of Iran and An-Iran, celestial germ of the race of gods, grandson of the excellent Narses, king of kings." The second inscription is as follows: "He of whom this is the figure is the adorer of Ormuzd, the excellent Vaharam, king of kings, of Iran and An-Iran, celestial germ of the race of gods, son of the servant of Ormuzd, the excellent Shapoor, king of kings, of Iran and An-Iran, celestial germ of the race of gods, grandson of the excellent Hoormuz, king of kings."

There are other monuments of antiquity both at Shapoor and at Persepolis, which belong to the era of the Sassanian kings, and which afford important and curious illustrations of these times. Fifteen miles north of Kauzeroon are the ruins of Shapoor, once the capital of Persia. At the entrance of the valley where it is situated stands an insulated hill, which exhibits portions of its ancient walls and towers; and the precipitous cliffs are carved with sculptures. On the southern side of the river which waters the plains, a much mutilated bas-relief is carved on the surface of the rock, consisting of two colossal equestrian figures. Their height appears to be about fifteen feet. A tablet, divided into three compartments, contains the second sculpture. In the central compartment is an equestrian figure, with the usual badges of Sassanian sovereignty. A suppliant is on his knees before the horse's head, his hands extended, and his face expressive of entreaty; whilst another figure with Egyptian features stands, likewise in the attitude of a suppliant, to the right of this compartment. The right-hand section contains three figures in attitudes of supplication. A greater number of tablets are still to be seen on the opposite side of the river. They contain various figures and designs, one of which is an elaborate representation of the triumph of a Persian over a Roman army. Colossal horsemen are pictured on others, with the royal emblems of Persia. In the Shapoor valley is a mountain, which is crowned by a perpendicular precipice of limestone 700 feet in height. Here is a cavern of enormous extent, its communication intricate and endless, with every form and variety of stalactites diversifying the different chambers, some of which are wonderfully lofty and spacious, and, when entered by torch-light, present the most brilliant reflection of all sorts of fantastic shapes. The entrance to the cave is about 140 feet above the base of the precipice; and here, in a spacious archway a hundred and fifty feet broad, and nearly forty feet in height, within which is a sort of natural anti-chamber, stands the pedestal of a statue, which lies mutilated and prostrate with the head downwards. Both have been cut out of the solid rock. The figure, which, when erect, must have been from fifteen to twenty feet in height, represents some one of the Sassanian kings, Shapoor as is supposed. There are various other Sassanian relics in the vicinity of Persepolis, namely, the tombs of the kings, where the sculptures, by the natives called Naksh-e-Roostum, are to be found; also the sculptures named Naksh-e-Rejib. The sculptures of Naksh-e-Roostum are contained in six tablets cut on the perpendicular rock, and containing many bas-reliefs of the triumphs or victories of the Persian arms under the Sassanian kings, with figures of the sovereign in various attitudes, and of horsemen engaged in hostile collision. The sculptures at Naksh-e-Rejib consist of three tablets, containing seven colossal and two diminutive figures. One of the sovereigns is on horseback in his greatest pomp, and underneath is a Greek inscription, which has been restored and translated by M. de Sacy. It runs thus: "This is the resemblance of the servant of Ormuzd, the divine Shapoor, king of kings, of Iran and An-Iran, of the race of the gods, son of the servant of Ormuzd, the divine Artaxares, king of kings, of Iran and An-Iran, of the race of gods, grandson of the divine Babec the king." The remaining tablet contains but a repetition of the two horsemen holding a ring.

There are other ancient monuments in different parts of Persia, consisting of sculptured rocks and other remains resembling druidical erections. For a particular account of these and the other relics of antiquity, which we have here briefly described, the reader is referred to Niebuhr, Chardin, Morier, Sir W. Ouseley, Sir R. K. Porter, and others. The sketch that we have given will suffice to illustrate generally the nature, as well as the beauty and art, which appear in these antiquarian remains.

The early history of Persia is lost in remote antiquity, and for authentic accounts the most extravagant fables have been substituted. These are chiefly the uncertain gleanings of oral tradition, or the fictions of poets. The work of Ferdousi, celebrated as the Homer of Persia, which, from the rudest materials, is amplified into a history of the Persian kings, comprises all the information possessed by the Asiatic writers prior to the Mahommedan conquest; nor are the prose chronicles of a later date one whit more authentic than the reveries of the poets. From these authorities Sir John Malcolm has compiled the early annals of Persia, to which we refer our readers for some account of that barbarous era. Arbaces is generally considered as having been the first sovereign of Media. He flourished in the year 747 before Christ, and conspired with Balesis, governor of Babylon, and other nobles, against Sardanapalus, with whose death terminated the Assyrian monarchy. Dejoces is by other writers held to have been the first sovereign of Persia. He was succeeded by his son Phraortes, who swayed the Persian sceptre twenty-two years. Learned writers have exercised their ingenuity to reconcile the names and dates of this obscure portion of Persian history. But amidst such manifold obscurities speculation seems to be useless, the truth being lost beyond the hope of recovery. The conquest of the country by Cyrus is the first era of Persian history which has the appearance of authenticity. Cyrus was the chief of a pastoral horde, who, quitting their own comparatively barren and unproductive country, subdued the territories of their wealthy and luxurious neighbours. He was the conqueror of Babylon; and on the ruins of that great kingdom he founded that of Persia, which was gradually extended by conquest from the Mediterranean to the Indus and the Oxus. Historians differ concerning the fate of this monarch. According to some, he was taken prisoner and put to death by the queen of the Massagetæ; whilst Xenophon affirms that he died in Persia, and was buried at Pasargada, in the year 529 before Christ. Cyrus was succeeded by Cambyses, the Ahasuerus of the Scriptures, who gave himself up to sensuality and cruelty. Still he extended his empire, having reduced Egypt to the state of a colony, and also conquered a great part of Northern Africa. Pseudo Smerdis, feigning himself to be the brother of Cambyses, who had been murdered, was by a faction of the Magi raised to the throne. Otanes, a Persian nobleman, finding out the deceit, conspired with six other chiefs, who agreed to assassinate him, which they effected, after he had reigned eight months. Along with him they put to death a number of the wise men; and, having decided on a monarchical form of government, they resolved to assemble next morning at sun-rise, without the city, on horseback; and it was agreed that he whose horse should neigh first should be chosen king. The well-known trick of Æbores, the groom of Darius Hystaspes, secured the throne to his master. He brought his master's horse the evening before, with a mare, to the appointed spot; and the horse, as soon as he arrived next morning, recollecting the mare, neighed, and he was immediately saluted king. It was during the reign of this monarch, who, according to Sir John Malcolm, is the king named Gushtah by the Persian historians, that the worship of fire was introduced into Persia by Zoroaster. The founder of this new religion is generally supposed to have lived during the reign of this prince, who was converted by his arts to the new faith, and who not only built temples for the worship of fire in every part of his dominions, but compelled his subjects to worship in them. The new faith, accordingly, spread rapidly, and its precepts were ordered to be written on 12,000 cow-hides, tanned fine for the purpose, which were deposited in a vault under the guardianship of holy men. Darius Hystaspes reigned over Persia sixty years, and was distinguished as a legislator as well as a conqueror. He divided the country into nineteen satrapies or provinces, each liable for the payment of a fixed tribute. Over these provinces satraps were sent to preside, with the delegated authority of the king. Their duties were to collect the revenue, to improve agriculture, and to perform all the royal commands. They were afterwards invested with military commands; and securities were devised against their usurpation of independent authority. An establishment of couriers was at the same time instituted, for expediting orders through every part of the empire. A regular and efficient military force was also organized by this monarch, and maintained at the expense of the different provinces. In process of time, Grecian mercenaries were taken into pay; and, when the country was engaged in war, the army was recruited from the people.

The reign of Darius was distinguished by several important warlike expeditions. Crossing the Thracian Bosphorus, he invaded Europe with 70,000 troops. But the Scythian tribes between the Danube and the Don successfully resisted his attack, and forced him to retreat with loss. He then overran the territories of Thrace and Macedonia, and thus began those attempts on the independence of Greece which were fraught with such disgrace to the Persian arms. He invaded the countries to the east of Persia with a powerful army, and added several extensive and rich provinces to his already overgrown empire; and his vast armies were also sent to overwhelm the rising communities of Greece. But his troops, though they far outnumbered their enemies, were here opposed by a firm and disciplined band of devoted patriots; and they were completely overthrown on the plains of Marathon by the forces of the Greeks, as inferior in number as they were superior in valour, in patriotism, and in every heroic quality. Amidst these disasters the reign of this monarch terminated, and he was succeeded by his son Xerxes.

The latter carried on a successful war against the Egyptians, whom he gave over to the vengeance of his brother Achæmenes; and he resolved to avenge himself on the Greeks, who had hitherto bravely defended their country against the numerous armies of Persia. With this view he fitted out a mighty armament, in which he embarked an army amounting to three millions of troops, or, with all the camp followers, to above 5,000,000; and with this vast force he resolved to annihilate the independence and liberties of Greece at a single blow. But he was met by the devoted bands of Grecian patriots, and experienced a severe check at the celebrated pass of Thermopylæ, which was defended by 300 Spartans against his whole army, and which he only carried by an immense sacrifice of men; and his fleet and army were finally overthrown at Salamis, Platæa, and Mycale, he himself escaping from the scene of action in a miserable fishing-boat. He was assassinated, after a reign, as some say, of twenty-one, or, according to others, of sixty years. But Sir John Malcolm is of opinion that this period includes also the two former reigns.

He was succeeded by his grandson Artaxerxes Longimanus, the Ardisheer Dirazdust or Long-shanks of the Persian historians. He is celebrated for the internal regulation of his empire, and for the intelligence which he acquired relative to all the concerns of the kingdom, by means of the agents whom he employed. He is represented by some as the Ahasuerus of the Scriptures, because he is said to have treated the Jews with lenity and kindness, and to have married one of that nation. But this is doubted by many, and does not well agree with other historical facts. This period of the Persian history is peculiarly obscure; and Sir John Malcolm observes, that the authors whom he follows become more fabulous as the history advances. The two succeeding sovereigns were Xerxes II. and Darius II., whose reigns were short. The latter was succeeded by Artaxerxes Memnon, his eldest son, who had to contend for the crown with his younger brother Cyrus. It was in his reign that the famous retreat of the ten thousand took place under Xenophon, who has given a narrative of the expedition. His reign, which continued twenty years, was a scene of intrigue, in which favourites bore the chief sway, and during which those symptoms of decay became visible which terminated at last in the overthrow of the kingdom. He was succeeded by Darius or Dorab I., who reigned only twelve years. In the year 336 B. C., Darius Codomanus, or Dorab II. of the Persian historians, assumed the sceptre; but he was totally unlike his father, being deformed in body, and not less so in mind. It was in his reign that Alexander of Macedonia, having subdued the different principalities of Greece, and consolidated their power into one, invaded Persia. He crossed the Hellespont in the year 334 B. C., with a well-disciplined and veteran force of 35,000 men, and encountered and defeated the Persian host on the banks of the Granicus. The hasty levies of Persia were again routed in the fatal battle of Issus, in which 100,000 were slain; and the family of Darius fell into the victor's hands. The battle of Arbela, which succeeded, completed the triumph of Alexander. The Persian armies were routed and dispersed, and the unfortunate Darius, flying from the field of battle, was seized by his nobles, at the head of whom was Bessus, who bound him in golden chains, and were carrying him to Bactriana in a car covered with skins; but being overtaken by the conqueror, they stabbed their victim to the heart, and left him in the chariot, weltering in his blood. He was found in the agonies of death by Polystrates, a Macedonian. The unhappy king asked for water, and with his last breath implored blessings on the head of Alexander, for his kindness to his wife, his mother, and his children. "Present," said he to Polystrates, "your hand to Alexander, as I do mine to you, the only pledge I have to give of gratitude and affection." The Greek and Persian accounts of the death of Darius do not materially differ, only that the latter are embellished by many circumstances, and also by fables, not related by the Greek or Roman historians. The body of the deceased king was embalmed with musk and amber, wrapt in a cloth of gold, and placed in a rich coffin adorned with jewels, and was in that state carried to the sepulchral vault, and interred with extraordinary honours. Exemplary justice was then executed on Bessus, the murderer of Darius, who, according to some, was hanged, but, according to others, torn in pieces by means of trees, which, being bent in a particular manner, were allowed to spring back to their natural position, and in this manner tore his body, which was fastened to them, in pieces. With Darius terminated the dynasty of Cyrus, which had subsisted 206 years under the following series of kings, as given by the Greek writers, with the periods of their several reigns. There is, however, no corresponding series given by the Persian historians, nor indeed any agreement between the narratives of the historians of the respective nations.

Greek Names of the Persian Kings.

Names.	Reigns.	Names.	Reigns.
1. Dejoces	53	10. Artaxerxes Longimanus	49
2. Phraortes	22	11. Darius Nothus	19
3. Cyaxares	40	12. Artaxerxes Memnon	46
4. Astyages	35	13. Ochus	21
5. Cyrus	30	14. Arses	2
6. Cambyses	25	15. Darius Codomanus	5
7. Smerdis the Magian	7		
8. Darius Hystaspes	36		
9. Xerxes	21		
			387

After the death of Alexander, Asia continued for a long period a scene of war and commotion, owing to the contests which arose amongst his successors for the dominion of the country. But about the year 307 B. C., Seleucus by his success had acquired the dominion of all the countries which lie between the Euphrates, the Indus, and the Oxus, and he had even carried his victorious arms to the Ganges, and established a friendly alliance with Sandrocottus, one of the sovereigns of these eastern countries. The Seleucidæ continued to sway the sceptre of this kingdom till the year 250 before the Christian era, when they were expelled from the throne by a successful revolt of the Parthians, who succeeded in establishing a new dynasty of kings. This revolution was effected by Arsaces, a noble of that country, who had been enraged by an affront offered to his brother Tiridates. Having assembled his friends, he put the tyrant to death; and, encouraged by his success, and by his increasing popularity, he openly aspired to the throne. He was mortally wounded, however, in a successful battle, in the moment of victory. His crown was inherited by his brother Tiridates, who laid the foundation of the Parthian dynasty. The Arsacidæ, as they are termed, from their founder, continued to rule in Persia for 430 years, namely, till the 230th year of the Christian era. The Persian annals during the whole of this period are very imperfect, and, according to Sir John Malcolm, that remarkable era of five centuries, from the death of Alexander till the reign of Artaxerxes, may be termed a blank in eastern history. The Parthian line of kings were illustrious, however, by their deeds, recorded in the authentic pages of the Greek and Roman historians. The Parthian empire extended, under its sixth monarch, Mithridates I., from the Euphrates to the Indus, and its monarchs were the only potentates who maintained a successful conflict with the Roman power. Pacorus, the ninth of the Arsacidæ, was the first Parthian king who had any intercourse with Rome. In the ninetieth year before the Christian era, he despatched an embassy to Sylla, at that time the Roman commander in Cappadocia; and it was thirty-seven years afterwards that the Roman troops under Crassus were destroyed by the Parthians. The Romans were not aware, until they were instructed by fatal experience, of the advantages possessed by the Parthians for defensive war, first, in the nature of their frontier, which from the Caspian Sea to the Persian Gulf presents a barrier of lofty mountains, rapid and broad streams, or wide-spreading deserts; and, secondly, in their peculiar tactics, by which the Parthian warrior took an unerring aim whilst he was retreating from his enemy. The Roman legions, surrounded, amidst those barren wastes, by clouds of cavalry, perished by the arrows of an enemy whom they could never reach. "The system," says Sir John Malcolm, "was suited to the soil, to the man, and to the fleet and robust animal on which he was mounted; and its success was so certain, that the bravest veterans of Rome murmured when their leaders talked of a Parthian war." The Parthians were so much elated with their victory, that they invaded and overran Syria and Asia Minor, and were at last overthrown by the Roman legions under Ventidius, the general of Antony. The latter, however, in an expedition undertaken against the Parthians in revenge for the defeat and death of Crassus, narrowly escaped the same fate; he succeeded, however, after a long and painful retreat, in placing the deep and rapid river of Aras or Araxes between him and the pursuing enemy, and thus effected his escape. Augustus, after he was seated on the imperial throne, threatened an invasion of Parthia. To avert this attack, Phraates, the fifteenth of the Arsacidæ, restored the standards which had been taken from Crassus. During the whole remaining period of this dynasty, which amounted to 200 years, the Romans were often at war with the Parthians; but they made no serious impression on their territories. Macrinus was involved, by the perfidy of Caracalla, whose successor he was, in a long and bloody war with the Parthian monarch Artabanes, who, after the war had terminated, as usual, by a treaty, was so weakened by his losses, that Artaxerxes, a Persian nobleman of great courage and influence with his countrymen, availed himself of the hereditary animosity of the Persians to stir up a rebellion against him. Arsaces took the field in defence of his crown, but was defeated in three battles, taken prisoner, and put to death, after which his rival ascended the throne, A. D. 226 ; and thus terminated the dynasty of the Arsacidæ, of whose line of kings a list is subjoined.

Dynasty of the Arsacidæ.

1. Arsaces I.
2. Tirides his brother.
3. Arsaces II.
4. Preapatius.
5. Phraates I.
6. Mithridates I.
7. Phraates II.
8. Artabanes I.
9. Pacorus I. who sent ambassadors to Sylla.
10. Phraates III.
11. Orodes I.
12. Mithridates II.
13. Phraates IV.
14. Phraatices.
15. Orodes II.
16. Venones I.
17. Artabanes II.
18. Tiridates.
19. Bardanes.
20. Gotarzes.
21. Miherdates.
22. Venones II.
23. Volgeses I.
24. Artabanes III.
25. Pacorus II.
26. Chosroes.
27. Parthanaspates.
28. Volgeses II.
29. Volgeses III.
30. Artabanes IV.

The Sassanian dynasty of kings forms a new era in the history of Persia. These monarchs were engaged in long and bloody wars with the Roman emperors ; and hence we are enabled to correct the imperfect records of the East by the authentic narrative of the Roman historians. The new monarch Artaxerxes, or Ardisheer as he is called by the Persian historians, having pacified the province of Fars, made himself master of Irak ; and having defeated and slain Aravan or Artabanes, who ruled over the mountainous country about Hamadan and Kermanshah, he was hailed in the field with the high title of Shah an Shah, or king of kings ; a name which has ever since been assumed by the sovereigns of Persia. In the course of his reign, which lasted fourteen years, he extended and consolidated his newly-acquired dominions, and waged, with various success, a war with the Roman emperor Alexander. He laboured to restore the religion of Zoroaster, and the authority of the Magi, which he enforced against all who opposed it, by the most sanguinary decrees. He was succeeded by his son Shapoor or Sapores, A. D. 242, who carried on a successful war against the Romans, whose emperor, Valerian, in an attempt to relieve Edessa, was defeated and taken prisoner. He gained many victories over the armies of that nation ; but towards the latter part of his reign he suffered reverses; his army was attacked by Odenathus, prince of Palmyra, and his country was afterwards invaded by Aurelian, the warlike emperor of Rome. Hoormuz his son, the Hormisdas of Greek authors, reigned only one year, and was succeeded by Baharam or Varanes, who evinced his zeal for the ancient religion of Persia by the execution of Mani, the founder of the sect of Manicheans. He reigned three years and three months, and was succeeded by Baharam II., who was a weak prince. During his reign of seventeen years, he engaged in a war with the Roman emperor Carus, who conquered Mesopotamia, carried his arms across the Tigris, and made himself master of Ctesiphon. Baharam III. reigned only three months. His brother Narsi (the Narses of the Greeks) reigned nine years, and abdicated the throne in favour of his son Hoormuz. He subdued Armenia, and signally defeated the Emperor Galerius on the same fatal field on which Crassus had been slain. The Romans invaded Persia next year, and defeated, with great slaughter, Narses, who fled, leaving his tents and family in possession of the conquerors. An inglorious peace followed, by which Mesopotamia and five districts to the eastward of the Tigris were ceded to the Romans. No events of any consequence occurred during the succeeding reign of Hoormuz II. the Misdates of the Greeks. He was succeeded by Shahpoor II. or Sapores, who was crowned king from his birth, and during a reign of seventy years maintained the integrity of his kingdom. His first operations were directed against the Arab tribes, on whom he took a severe vengeance for having invaded his territories. He was involved in bloody wars with the Romans, in the course of which he experienced serious reverses. Constantine advanced into Persia with a formidable army, and was joined by the Arab forces. A dreadful conflict took place, in which the Persian army was routed with great slaughter, and the king himself narrowly escaped, with a few followers, from the fatal field. But having recruited his army, he again took the field, and, in a night attack, he recovered some of the advantages which he had lost. He was also successful in repelling the invasion of Julian, who was killed by an arrow, and his successor Jovian was fain to purchase a peace by the loss of all the provinces east of the Tigris, which had been ceded in the former reign. Shahpoor reigned during his whole life, which was seventy-one years. Ardisheer II., or Artaxerxes, succeeded, and was deposed by Shahpoor, the son of the late monarch, after a reign of four years. He reigned only five years, when he was killed by the fall of a tent, which was blown down by one of those whirlwinds which sometimes occur in Persia. Baharam IV. or Varanes, who succeeded, reigned eleven years, and was at length killed by an arrow, in endeavouring to quell a tumult in his army. The throne of Persia was next filled by Yezdijird, the Greek Isdigertes. He is very differently represented by the Persians and Greeks ; by the former as cruel and abandoned to luxury, and by the latter as wise and virtuous. He was killed by a kick of his horse, after a reign of sixteen years. Baharam Gour, or Varanes V. succeeded. He is celebrated for his munificence and generosity. His dominions were invaded, and partly overrun, by the Tartars, who, being flushed with their conquest, gave themselves over to a false security, and were one night surprised and defeated with great slaughter by Varanes. The only fruit which he sought from this victory was peace with all his neighbours, after which he returned to his capital. He was engaged in wars with the Romans under Theodosius, in which neither party had any cause to boast. His ruling passion was the chase, and he was fond of hunting the wild ass ; and it was in pursuit of one of these animals that he lost his life, in a deep pool, where neither he nor his horse were ever again seen. He was succeeded by his son Yezdijird II., or Varanes VI., who followed his father's footsteps, and, during his reign of eighteen years, was only once engaged in war with the Romans. The succession to the throne was now disputed between Hoormuz (Peroses) the younger son of Yezdijird, who was appointed heir by his father, and Ferose (Varens IV.) the elder, who, being supported by an army of Tartars, to whose king he fled for support, and by the chief nobles, succeeded in wresting the sceptre from his brother's hand, and in putting him to death, after reigning a year. He lost his life in an expedition which he undertook against the Tartar prince, by whom he had been treated with so much generosity. Pallas, the son of Ferose (Cavades), now ascended the throne, and was succeeded by Kobad, who, though he was dethroned by his discontented subjects, reconquered his lost dignity. He carried on a successful war with Anastasius the Roman emperor, and died after a long and diversified reign of forty-three years.
